

Digital Design & Computer Arch.

Lecture 15b: Out-of-Order Execution

Prof. Onur Mutlu

ETH Zürich
Spring 2021
23 April 2021

Required Readings

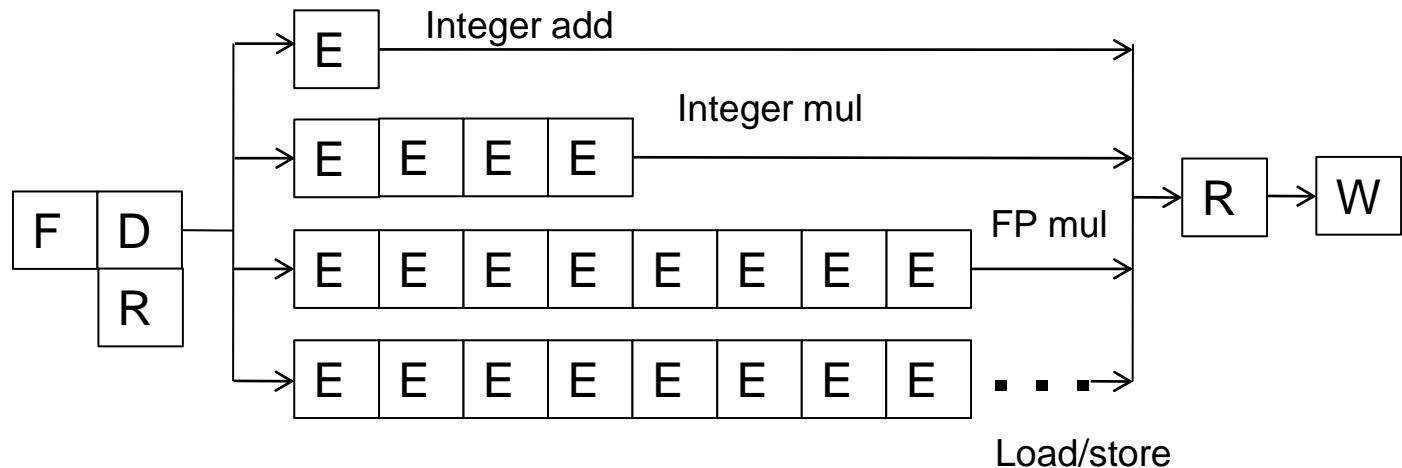

- This week & Next Week
 - Out-of-order execution
 - H&H, Chapter 7.8-7.9
 - Smith and Sohi, “The Microarchitecture of Superscalar Processors,” Proceedings of the IEEE, 1995
 - More advanced pipelining
 - Interrupt and exception handling
 - Out-of-order and superscalar execution concepts
- Optional
 - Kessler, “The Alpha 21264 Microprocessor,” IEEE Micro 1999.
- Next Week
 - McFarling, “Combining Branch Predictors,” DEC WRL Technical Report, 1993.

Agenda for Today & Next Few Lectures

- Single-cycle Microarchitectures
 - Multi-cycle and Microprogrammed Microarchitectures
 - Pipelining
 - Issues in Pipelining: Control & Data Dependence Handling, State Maintenance and Recovery, ...
 - Out-of-Order Execution
 - Other Execution Paradigms
-

Review: In-Order Pipeline with Reorder Buffer

- **Decode (D)**: Access regfile/ROB, allocate entry in ROB, check if instruction can execute, if so **dispatch** instruction (send to functional unit)
- **Execute (E)**: Instructions can complete out-of-order
- **Completion (R)**: Write result **to reorder buffer**
- **Retirement/Commit (W)**: Check for exceptions; if none, write result to architectural register file or memory; else, flush pipeline and start from exception handler
- **In-order dispatch/execution, out-of-order completion, in-order retirement**

Recall: Data Dependence Types

True (flow) dependence

$$\begin{array}{l} r_3 \leftarrow r_1 \text{ op } r_2 \\ r_5 \leftarrow r_3 \text{ op } r_4 \end{array}$$

Read-after-Write
(RAW) -- **True**

Anti dependence

$$\begin{array}{l} r_3 \leftarrow r_1 \text{ op } r_2 \\ r_1 \leftarrow r_4 \text{ op } r_5 \end{array}$$

Write-after-Read
(WAR) -- **Anti**

Output-dependence

$$\begin{array}{l} r_3 \leftarrow r_1 \text{ op } r_2 \\ r_5 \leftarrow r_3 \text{ op } r_4 \\ r_3 \leftarrow r_6 \text{ op } r_7 \end{array}$$

Write-after-Write
(WAW) -- **Output**

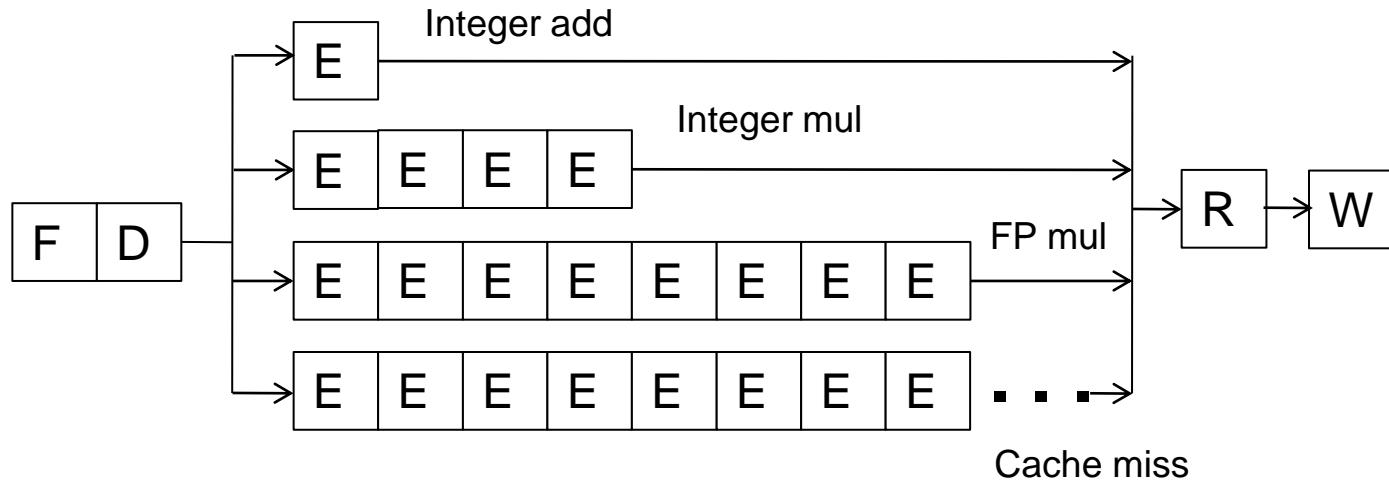

Remember: Register Renaming with a Reorder Buffer

- Output and anti dependencies are **not true dependencies**
 - WHY? The same register refers to values that have nothing to do with each other
 - **They exist due to lack of register ID's (i.e. names) in the ISA**
- The register ID is **renamed** to the reorder buffer entry that will hold the register's value
 - Register ID → ROB entry ID
 - Architectural register ID → Physical register ID
 - After renaming, ROB entry ID used to refer to the register
- This eliminates anti and output dependencies
 - Gives the illusion that there are a large number of registers

Out-of-Order Execution (Dynamic Instruction Scheduling)

An In-order Pipeline

- Dispatch: Act of sending an instruction to a functional unit
- Renaming with ROB eliminates stalls due to false dependencies
- Problem: A true data dependency stalls dispatch of younger instructions into functional (execution) units

Can We Do Better?

How Can We Do Better?

- What do the following two pieces of code have in common (with respect to execution in the previous design)?

```
IMUL R3 ← R1, R2  
ADD R3 ← R3, R1  
ADD R4 ← R6, R7  
IMUL R5 ← R6, R8  
ADD R7 ← R9, R9
```

```
LD   R3 ← R1 (0)  
ADD R3 ← R3, R1  
ADD R4 ← R6, R7  
IMUL R5 ← R6, R8  
ADD R7 ← R9, R9
```

- Answer: First ADD stalls the whole pipeline!
 - ADD cannot dispatch because its source registers unavailable
 - Later **independent** instructions cannot get executed
- How are the above code portions different?
 - Answer: Load latency is variable (unknown until runtime)
 - What does this affect? Think compiler vs. microarchitecture

Preventing Dispatch Stalls

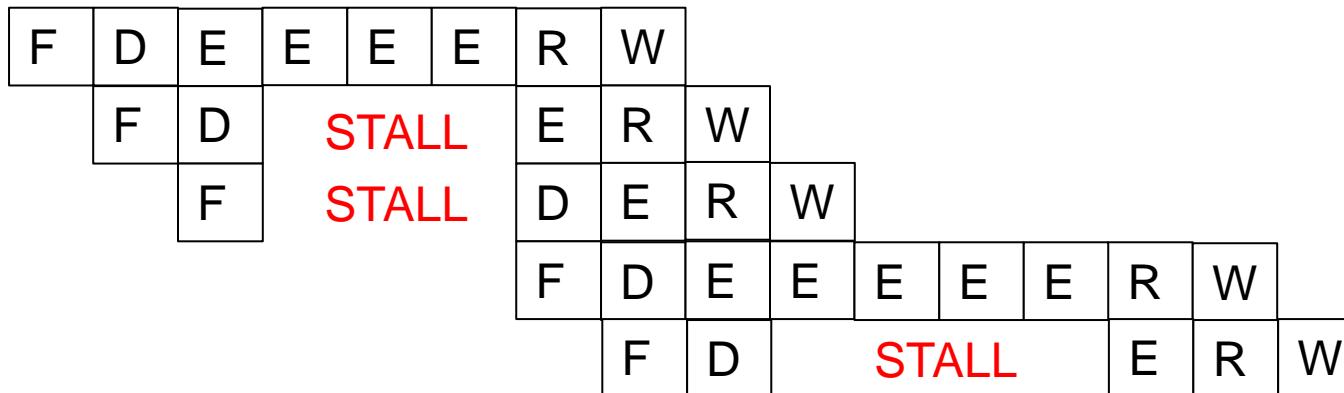

- Problem: **in-order** dispatch (scheduling, or execution)
- Solution: **out-of-order** dispatch (scheduling, or execution)
- Actually, we have seen the basic idea before:
 - **Dataflow**: “fire” an instruction only when its inputs are ready
 - We will use similar principles, but not expose it in the ISA
- Aside: Any other way to prevent dispatch stalls?
 1. Compile-time instruction scheduling/reordering
 2. Value prediction
 3. Fine-grained multithreading

Out-of-order Execution (Dynamic Scheduling)

- Idea: Move the dependent instructions out of the way of independent ones (s.t. independent ones can execute)
 - Rest areas for dependent instructions: Reservation stations
- Monitor the source “values” of each instruction in the resting area
- When all source “values” of an instruction are available, “fire” (i.e. dispatch) the instruction
 - Instructions dispatched in dataflow (not control-flow) order
- Benefit:
 - Latency tolerance: Allows independent instructions to execute and complete in the presence of a long-latency operation

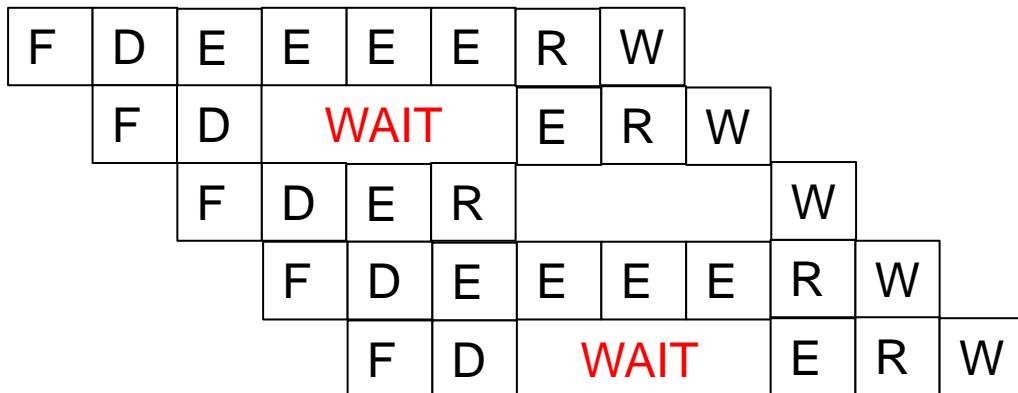

In-order vs. Out-of-order Dispatch

- In order dispatch + precise exceptions:

IMUL R3 \leftarrow R1, R2
ADD R3 \leftarrow R3, R1
ADD R1 \leftarrow R6, R7
IMUL R5 \leftarrow R6, R8
ADD R7 \leftarrow R3, R5

- Out-of-order dispatch + precise exceptions:

- 16 vs. 12 cycles

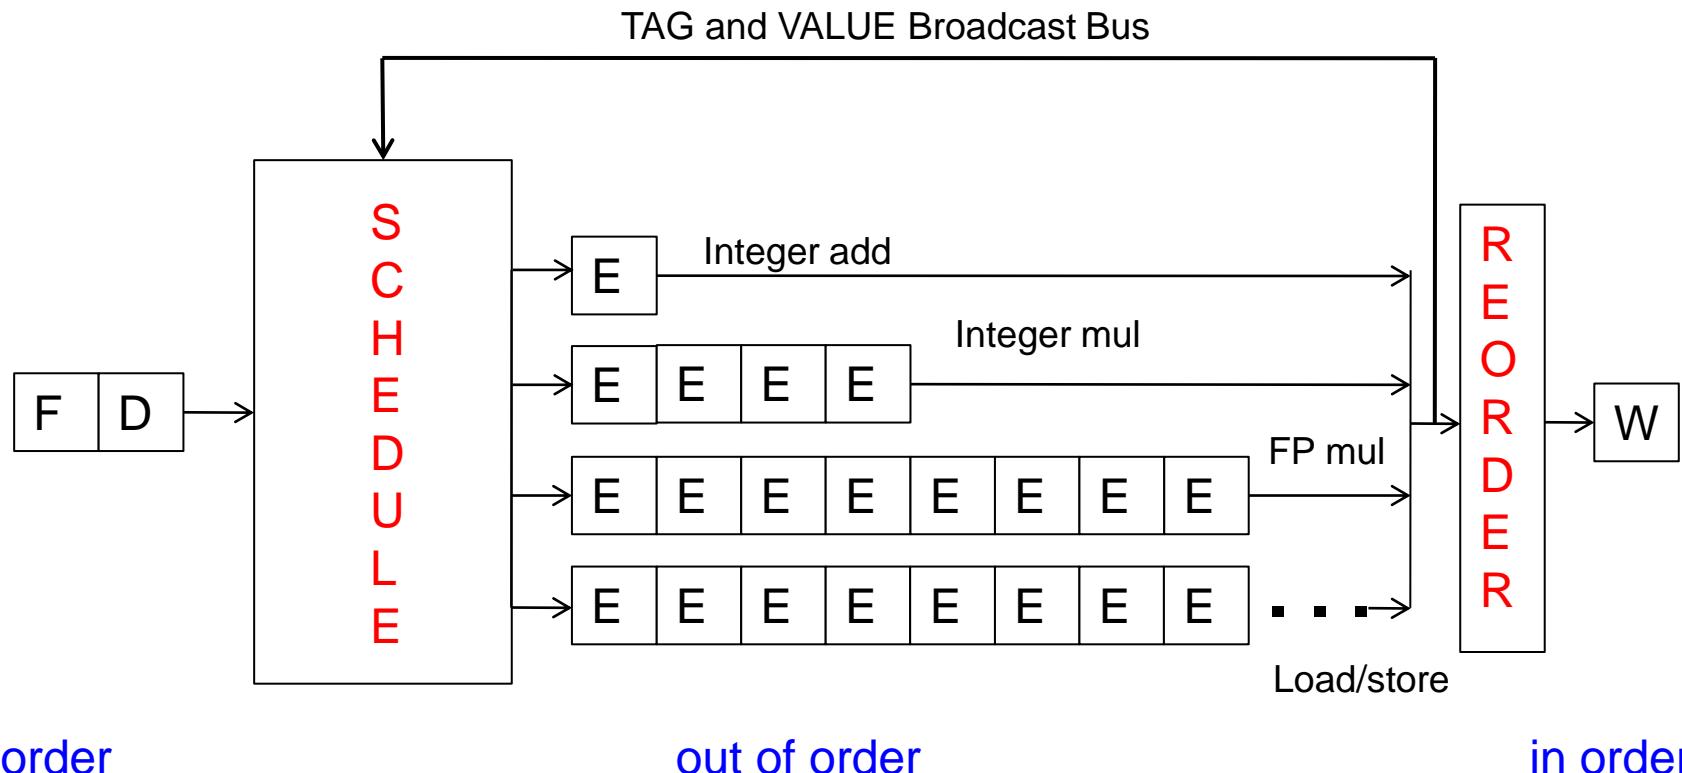

Enabling OoO Execution

1. Need to link the consumer of a value to the producer
 - ❑ Register renaming: Associate a “tag” with each data value
2. Need to buffer instructions until they are ready to execute
 - ❑ Insert instruction into reservation stations after renaming
3. Instructions need to keep track of readiness of source values
 - ❑ Broadcast the “tag” when the value is produced
 - ❑ Instructions compare their “source tags” to the broadcast tag
→ if match, source value becomes ready
4. When all source values of an instruction are ready, need to dispatch the instruction to its functional unit (FU)
 - ❑ Instruction wakes up if all sources are ready
 - ❑ If multiple instructions are awake, need to select one per FU

Tomasulo's Algorithm for OoO Execution

- OoO with register renaming invented by Robert Tomasulo
 - Used in IBM 360/91 Floating Point Units
 - **Read:** Tomasulo, “**An Efficient Algorithm for Exploiting Multiple Arithmetic Units,**” IBM Journal of R&D, Jan. 1967.
 - What is the major difference today?
 - Precise exceptions
 - Provided by
 - Patt, Hwu, Shebanow, “**HPS, a new microarchitecture: rationale and introduction,**” MICRO 1985.
 - Patt et al., “**Critical issues regarding HPS, a high performance microarchitecture,**” MICRO 1985.
 - OoO variants are used in most high-performance processors
 - Initially in Intel Pentium Pro, AMD K5
 - Alpha 21264, MIPS R10000, IBM POWER5, IBM z196, Oracle UltraSPARC T4, ARM Cortex A15
-

Two Humps in a Modern Pipeline

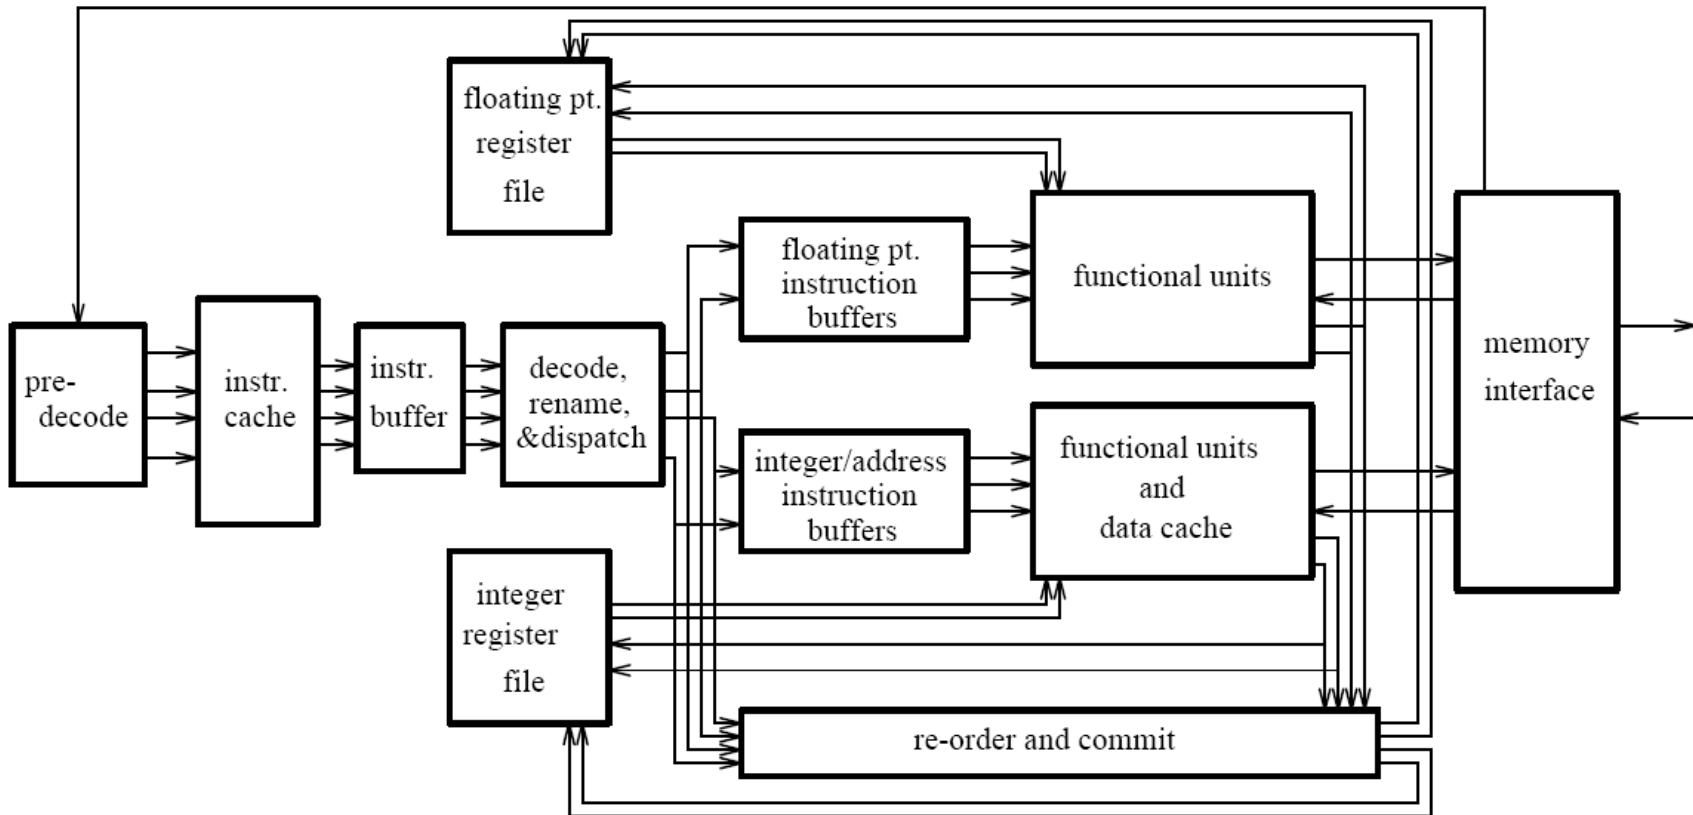

- Hump 1: Reservation stations (scheduling window)
- Hump 2: Reordering (reorder buffer, aka instruction window or active window)

Two Humps in a Modern Pipeline

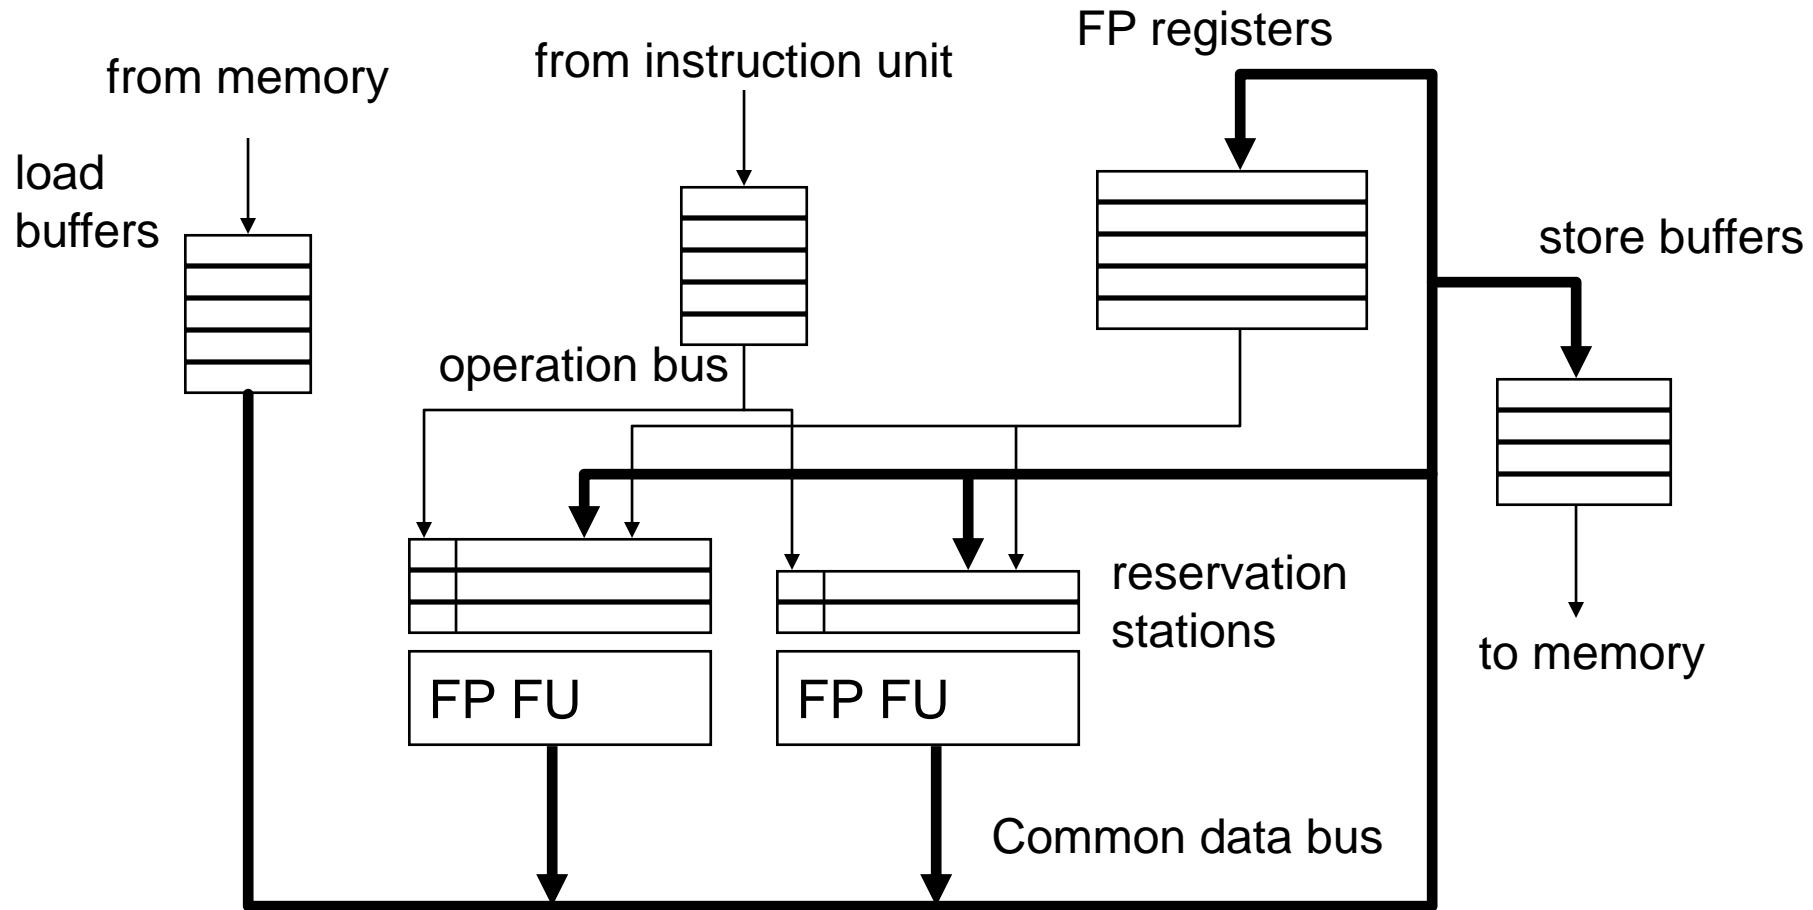

General Organization of an OOO Processor

- Smith and Sohi, “**The Microarchitecture of Superscalar Processors**,” Proc. IEEE, Dec. 1995.

Tomasulo's Machine: IBM 360/91

Recall Once More: Register Renaming

- Output and anti dependencies are not true dependencies
 - WHY? The same register refers to values that have nothing to do with each other
 - **They exist because not enough register ID's (i.e. names) in the ISA**
- The register ID is **renamed** to the reservation station entry that will hold the register's value
 - Register ID → RS entry ID
 - Architectural register ID → Physical register ID
 - After renaming, RS entry ID used to refer to the register
- This eliminates anti- and output- dependencies
 - Approximates the performance effect of a large number of registers even though ISA has a small number

Tomasulo's Algorithm: Renaming

- Register rename table (register alias table)

	tag	value	valid?
R0			1
R1			1
R2			1
R3			1
R4			1
R5			1
R6			1
R7			1
R8			1
R9			1

Tomasulo's Algorithm

- If reservation station available before renaming
 - Instruction + renamed operands (source value/tag) inserted into the reservation station
 - Only rename if reservation station is available
- Else stall
- While in reservation station, each instruction:
 - Watches common data bus (CDB) for tag of its sources
 - When tag seen, grab value for the source and keep it in the reservation station
 - When both operands available, instruction ready to be dispatched
- Dispatch instruction to the Functional Unit when instruction is ready
- After instruction finishes in the Functional Unit
 - Arbitrate for CDB
 - Put tagged value onto CDB (tag broadcast)
 - Register file is connected to the CDB
 - Register contains a tag indicating the latest writer to the register
 - If the tag in the register file matches the broadcast tag, write broadcast value into register (and set valid bit)
 - Reclaim rename tag
 - no valid copy of tag in system!

An Exercise

MUL R3 \leftarrow R1, R2

ADD R5 \leftarrow R3, R4

ADD R7 \leftarrow R2, R6

ADD R10 \leftarrow R8, R9

MUL R11 \leftarrow R7, R10

ADD R5 \leftarrow R5, R11

- Assume ADD (4 cycle execute), MUL (6 cycle execute)
- Assume one adder and one multiplier
- How many cycles
 - in a non-pipelined machine
 - in an in-order-dispatch pipelined machine with imprecise exceptions (no forwarding and full forwarding)
 - in an out-of-order dispatch pipelined machine imprecise exceptions (full forwarding)

Exercise Continued

MUL R1,R2, \rightarrow R3
ADD R3,R4 \rightarrow R5
ADD R2,R6 \rightarrow R7
ADD R8,R9 \rightarrow R10
MUL R7,R10 \rightarrow R11
ADD R5,R11 \rightarrow R5

Pipeline structure

F D E W
↓

can take
multiple
cycles.

MUL takes 6 cycles
ADD takes 4 cycles

How many cycles total w/o data forwarding?
" " " " " w/ " " ?

Exercise Continued

FD-----D1234W

F-----D1234W

FD1234W

FD---D123456W

F----D

D1234W

Execution timeline w/ scoreboarding

31 cycles

FD123456W

FD → E, D1234W

F D 1 2 3 4 W

F D 1 2 3 4 W

FD → 1 2 3 4, 5 6 W

F D → 1 2 3 4 W

25 cycles

Exercise Continued

```
MUL R3 ← R1, R2  
ADD R5 ← R3, R4  
ADD R7 ← R2, R6  
ADD R10 ← R8, R9  
MUL R11 ← R7, R10  
ADD R5 ← R5, R11
```

F D 1 2 3 4 5 6 W
F D → 1 2 3 4 W
F D 1 2 3 4 W
F D 1 2 3 4 W
F D → 1 2 3 4 5 6 W
F D → 1 2 3 4 W

Tomasulo's algorithm + full forwarding

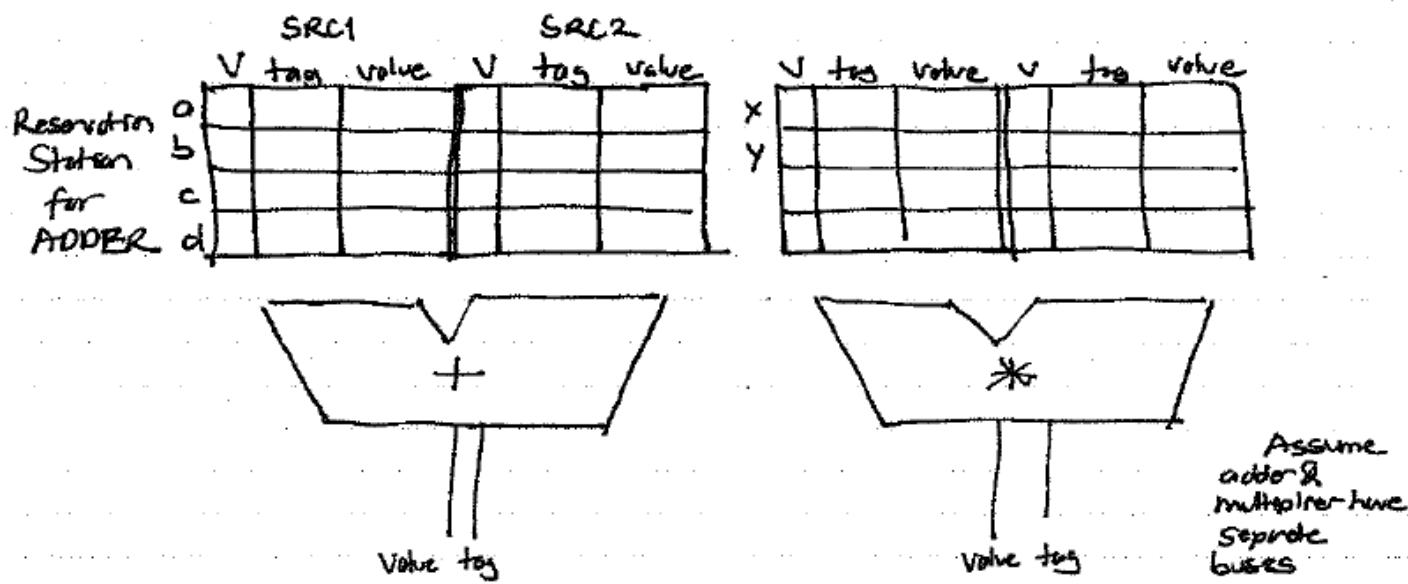

20 cycles

How It Works

Register Alias Table

V	Tag	Value

of writer

Our First OoO Machine Simulation

Program We Will Simulate

```
MUL R1, R2 → R3  
ADD R3, R4 → R5  
ADD R2, R6 → R7  
ADD R8, R9 → R10  
MUL R7, R10 → R11  
ADD R5, R11 → R5
```

Register	Valid	Tag	Value

Cycle 2

		Cycle 1	Cycle 2
MUL	R1, R2 → R3	F	D
ADD	R3, R4 → R5	F	F
ADD	R2, R6 → R7		
ADD	R8, R9 → R10		
MUL	R7, R10 → R11		
ADD	R5, R11 → R5		

MUL gets decoded and allocated into RS x

Step 1: Check if reservation station available. Yes: x

Step 2: Access *the Register Alias Table*

Step 3: Put source registers into reservation station x.

Step 4: Rename destination register R3 → x

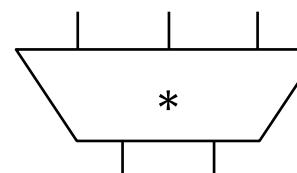

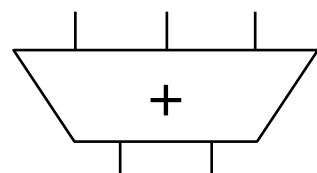

R3 is now renamed to x.

Its new value will be produced by the *reservation station* that is identified by tag x.

Register	Valid	Tag	Value
R1	1		1
R2	1		2
R3	0	x	
R4	1		4
R5	1		5
R6	1		6
R7	1		7
R8	1		8
R9	1		9
R10	1		10
R11	1		11

	Source 1			Source 2

a						
b						
c						
d						

	Source 1			Source 2		
	V	Tag	Value	V	Tag	Value
x		~			~	
y						
z						
t						

MUL in RS x is ready to execute in the next cycle!

Cycle 3

1. MUL in RS x starts executing

2. ADD gets decoded and allocated into RS a

	Cycle		
	1	2	3
MUL	R1, R2 → R3		F
ADD	R3, R4 → R5	D	E ₁
ADD	R2, R6 → R7	F	D
ADD	R8, R9 → R10		F
MUL	R7, R10 → R11		
ADD	R5, R11 → R5		

Register	Valid	Tag	Value
R1	1		1
R2	1		2
R3	0	x	
R4	1		4
R5	0	a	
R6	1		6
R7	1		7
R8	1		8
R9	1		9
R10	1		10
R11	1		11

Check readiness (Both sources ready?) → Wakeup

Ready → Dispatch the instruction to the MUL unit

Same Steps 1-4 for ADD... Rename R5 → a

ADD in RS a cannot execute in the next cycle: one source is not valid

Cycle 4

		Cycle	1	2	3	4
MUL	R1, R2 → R3	F	D	E ₁	E ₂	
ADD	R3, R4 → R5	F	D	-		
ADD	R2, R6 → R7	F	D			
ADD	R8, R9 → R10					F
MUL	R7, R10 → R11					
ADD	R5, R11 → R5					

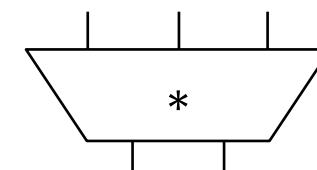

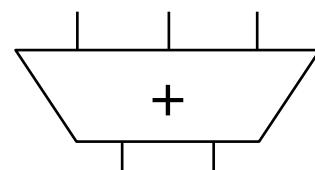

ADD in RS a waits because one source is not valid.

Rename R7 → b

Register	Valid	Tag	Value
R1	1		1
R2	1		2
R3	0	x	
R4	1		4
R5	0	a	
R6	1		6
R7	0	b	
R8	1		8
R9	1		9
R10	1		10
R11	1		11

Some Questions

- What is needed in hardware to perform tag broadcast and value capture?
 - make a value valid
 - wake up an instruction
- Does the tag have to be the ID of the Reservation Station Entry?
- What can potentially become the critical path?
 - Tag broadcast → value capture → instruction wake up
- How can you reduce the potential critical paths?

Dataflow Graph for Our Example

Corresponding Dataflow Graph (Reverse Engineered)

MUL R1, R2 → R3 (x)
ADD R3, R4 → R5 (a)
ADD R2, R6 → R7 (b)
ADD R8, R9 → R10 (c)
MUL R7, R10 → R11 (y)
ADD R5, R11 → R5 (d)

Dataflow graph

Nodes: operations performed by the instruction

Arches: tags in Tomasulo's algorithm

Some More Questions (Design Choices)

- When is a reservation station entry deallocated?
 - Should the reservation stations be dedicated to each functional unit or global across functional units?
 - Centralized vs. Distributed: What are the tradeoffs?
 - Should reservation stations and ROB store data values or should there be a centralized physical register file where all data values are stored?
 - What are the tradeoffs?
 - Timing: Exactly when does an instruction broadcast its tag?
 - Many other design choices for OoO engines
-

For You: An Exercise, w/ Precise Exceptions

MUL R3 ← R1, R2

ADD R5 ← R3, R4

ADD R7 ← R2, R6

ADD R10 ← R8, R9

MUL R11 ← R7, R10

ADD R5 ← R5, R11

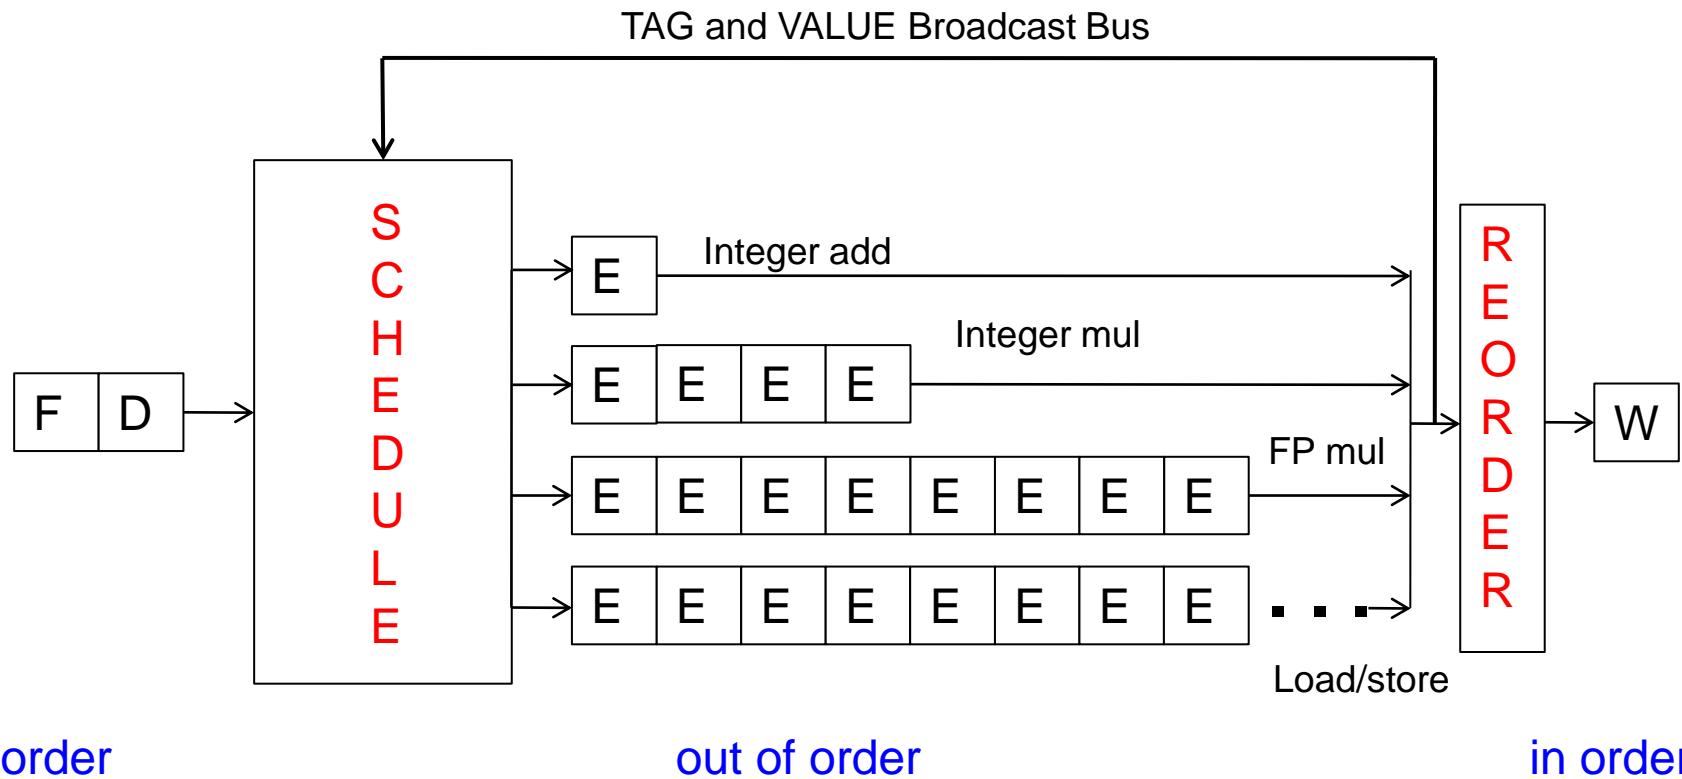

- Assume ADD (4 cycle execute), MUL (6 cycle execute)
- Assume one adder and one multiplier
- How many cycles
 - in a non-pipelined machine
 - in an in-order-dispatch pipelined machine with reorder buffer (no forwarding and full forwarding)
 - in an out-of-order dispatch pipelined machine with reorder buffer (full forwarding)

Out-of-Order Execution with Precise Exceptions

- **Idea:** Use a reorder buffer to reorder instructions before committing them to architectural state
 - An instruction updates the RAT when it completes execution
 - Also called **frontend register file**
 - An instruction updates a **separate** architectural register file when it retires
 - i.e., when it is the oldest in the machine and has completed execution
 - In other words, **the architectural register file is always updated in program order**
 - On an exception: flush pipeline, copy architectural register file into frontend register file
-

Out-of-Order Execution with Precise Exceptions

- Hump 1: Reservation stations (scheduling window)
- Hump 2: Reordering (reorder buffer, aka instruction window or active window)

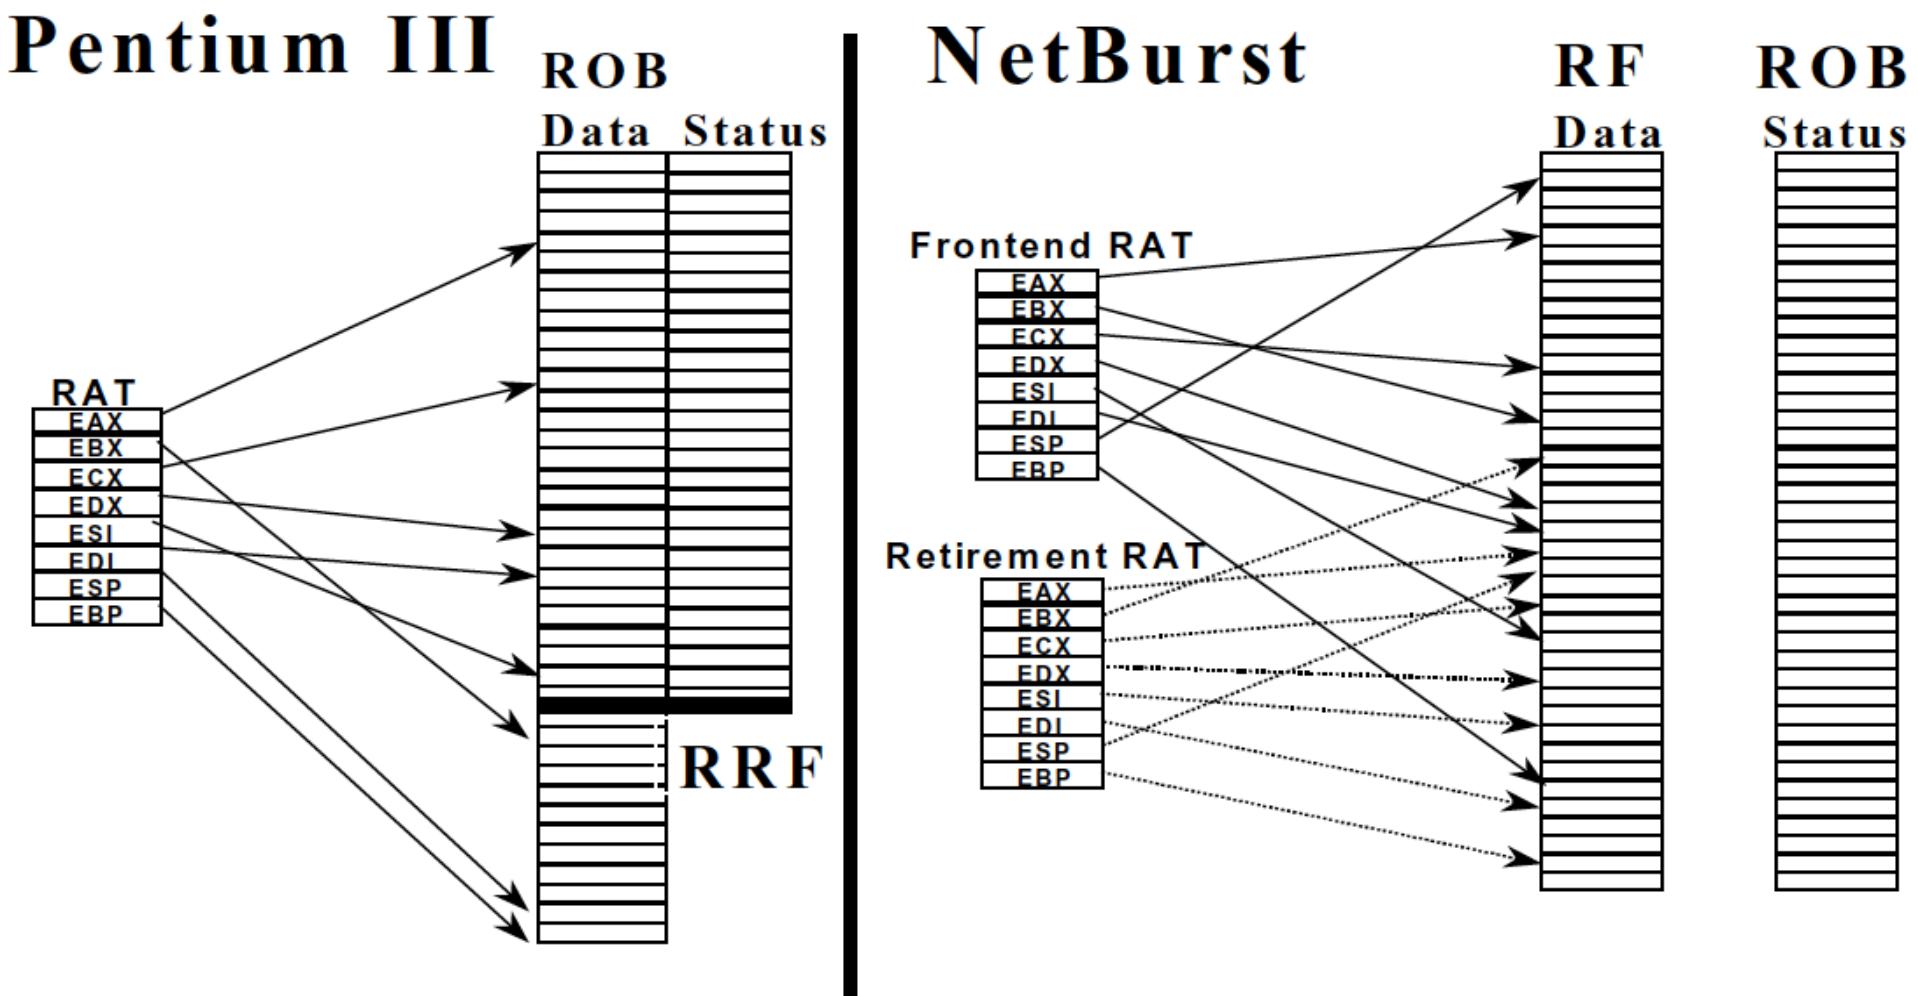

Two Humps in a Modern Pipeline

Modern OoO Execution w/ Precise Exceptions

- Most modern processors use the following
- Reorder buffer to support in-order retirement of instructions
- A single register file to store all registers
 - Both speculative and architectural registers
 - INT and FP are still separate
- Two register maps
 - Future/frontend register map → used for renaming
 - Architectural register map → used for maintaining precise state

An Example from Modern Processors

Boggs et al., "The Microarchitecture of the Pentium 4 Processor,"
Intel Technology Journal, 2001.

Enabling OoO Execution, Revisited

1. **Link** the consumer of a value to the producer
 - ❑ **Register renaming:** Associate a “tag” with each data value
2. **Buffer** instructions until they are ready
 - ❑ Insert instruction into **reservation stations** after renaming
3. Keep **track** of **readiness** of source values of an instruction
 - ❑ **Broadcast** the “tag” when the value is produced
 - ❑ Instructions **compare** their “source tags” to the broadcast tag
→ if match, source value becomes ready
4. When all source values of an instruction are ready, **dispatch** the instruction to functional unit (FU)
 - ❑ **Wakeup and select/schedule** the instruction

Summary of OOO Execution Concepts

- Register renaming eliminates false dependencies, enables linking of producer to consumers
- Buffering in reservation stations enables the pipeline to move for independent instructions
- Tag broadcast enables communication (of readiness of produced value) between instructions
- Wakeup and select enables out-of-order dispatch

OOO Execution: Restricted Dataflow

- An out-of-order engine dynamically builds the dataflow graph of a piece of the program
 - which piece?
 - The dataflow graph is limited to the **instruction window**
 - Instruction window: all decoded but not yet retired instructions
 - Can we do it for the whole program?
 - Why would we like to?
 - In other words, how can we have a large instruction window?
 - Can we do it efficiently with Tomasulo's algorithm?
-

Nodes: operations performed by the instruction

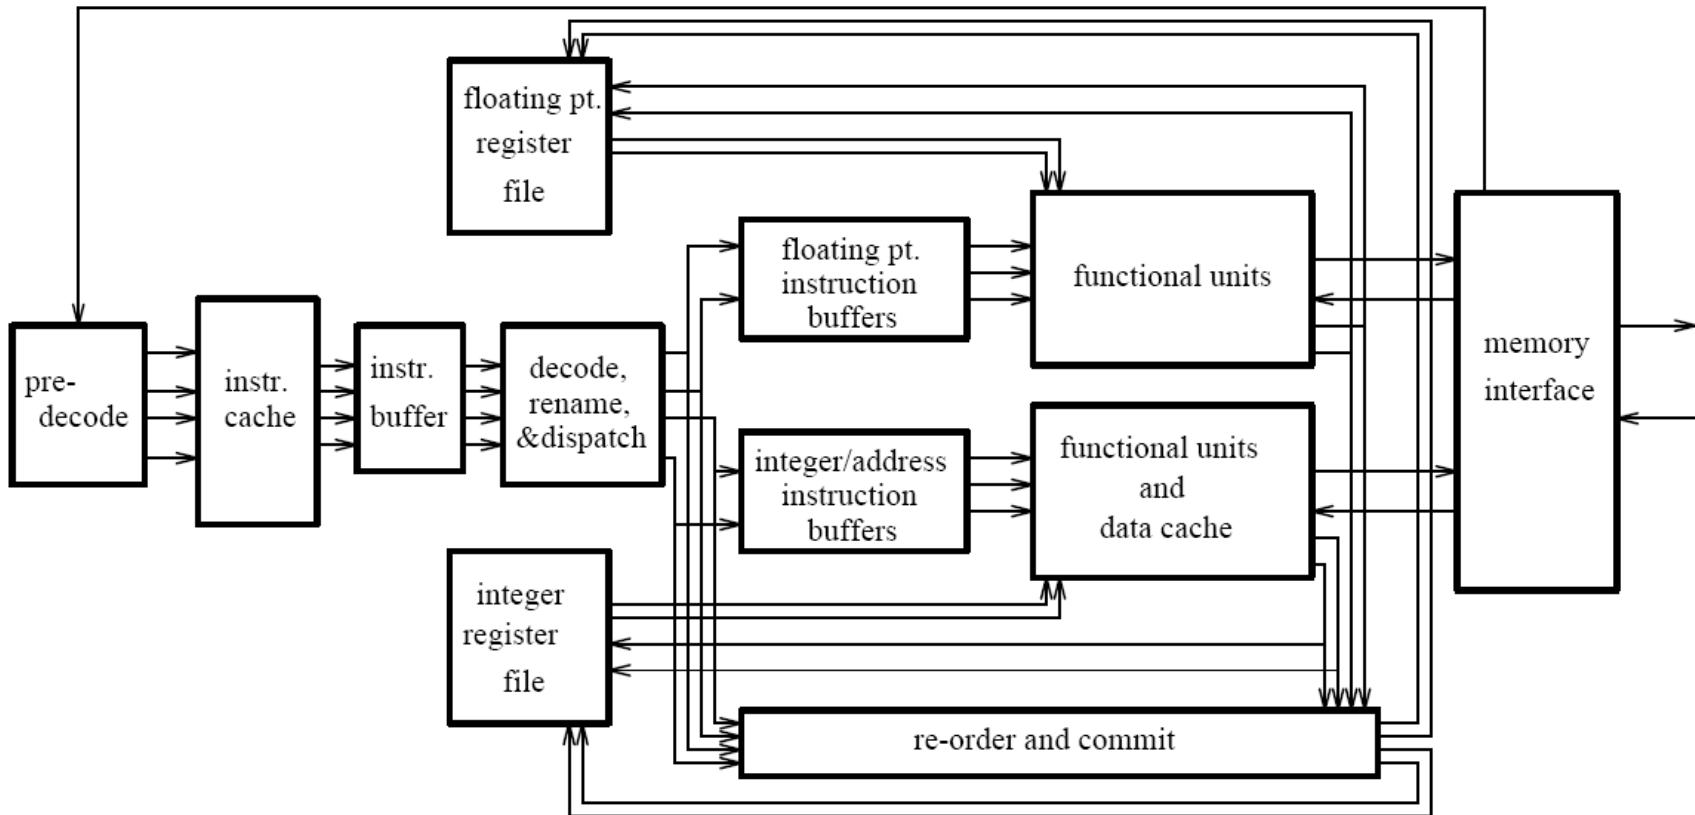

Arches: tags in Tomasulo's algorithm

Questions to Ponder

- Why is OoO execution beneficial?
 - What if all operations take a single cycle?
 - **Latency tolerance:** OoO execution tolerates the latency of multi-cycle operations by executing independent operations concurrently
- What if an instruction takes 1000 cycles?
 - How large of an instruction window do we need to continue decoding?
 - How many cycles of latency can OoO tolerate?
 - **What limits the latency tolerance scalability of Tomasulo's algorithm?**
 - **Instruction window size:** how many decoded but not yet retired instructions you can keep in the machine.

General Organization of an OOO Processor

“POWER4 system
microarchitecture,”
IBM J R&D, 2002.

IBM POWER4

- 2 cores, out-of-order execution
- 100-entry instruction window in each core
- 8-wide instruction fetch, issue, execute
- Large, local+global hybrid branch predictor
- 1.5MB, 8-way L2 cache
- Aggressive stream based prefetching

Handling Out-of-Order Execution of Loads and Stores

Registers versus Memory

- So far, we considered mainly registers as part of state
- What about memory?
- What are the fundamental differences between registers and memory?
 - Register dependences known statically – memory dependences determined dynamically
 - Register state is small – memory state is large
 - Register state is not visible to other threads/processors – memory state is shared between threads/processors (in a shared memory multiprocessor)

Memory Dependence Handling (I)

- Need to obey memory dependences in an out-of-order machine
 - and need to do so while providing high performance
- Observation and Problem: Memory address is not known until a load/store executes
- Corollary 1: Renaming memory addresses is difficult
- Corollary 2: Determining dependence or independence of loads/stores has to be handled *after* their (partial) execution
- Corollary 3: When a load/store has its address ready, there may be older/younger stores/loads with unknown addresses in the machine

Memory Dependence Handling (II)

- When do you schedule a load instruction in an OOO engine?
 - Problem: A younger load can have its address ready before an older store's address is known
 - Known as the **memory disambiguation** problem or the **unknown address** problem
- Approaches
 - **Conservative:** Stall the load until all previous stores have computed their addresses (or even retired from the machine)
 - **Aggressive:** Assume load is independent of unknown-address stores and schedule the load right away
 - **Intelligent:** Predict (with a more sophisticated predictor) if the load is dependent on any unknown address store

Handling of Store-Load Dependencies

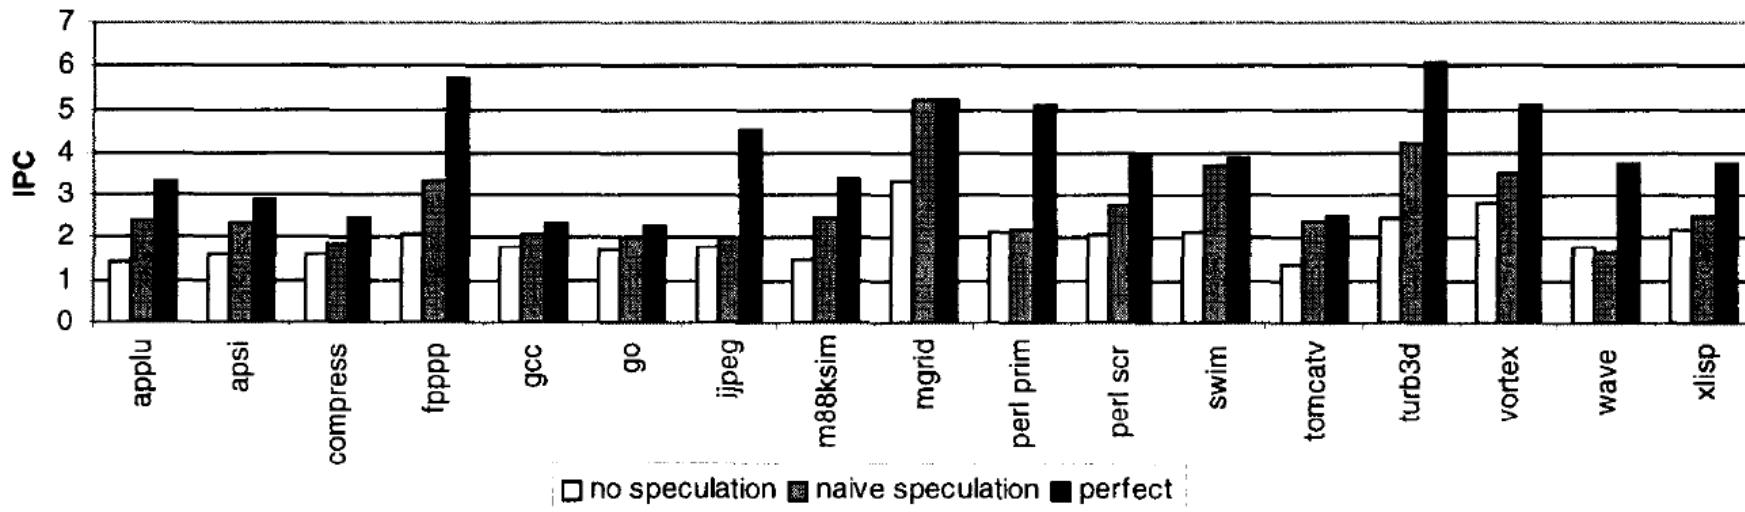

- **A load's dependence status is not known** until all previous store addresses are available.
- How does the OOO engine detect dependence of a load instruction on a previous store?
 - Option 1: Wait until all previous stores committed (no need to check for address match)
 - Option 2: Keep a list of pending stores in a store buffer and check whether load address matches a previous store address
- How does the OOO engine treat the scheduling of a load instruction wrt previous stores?
 - Option 1: Assume load dependent on all previous stores
 - Option 2: Assume load independent of all previous stores
 - Option 3: Predict the dependence of a load on an outstanding store

Memory Disambiguation (I)

- Option 1: Assume load is dependent on all previous stores
 - + No need for recovery
 - Too conservative: delays independent loads unnecessarily
- Option 2: Assume load is independent of all previous stores
 - + Simple and can be common case: no delay for independent loads
 - Requires recovery and re-execution of load and dependents on misprediction
- Option 3: Predict the dependence of a load on an outstanding store
 - + More accurate. Load store dependencies persist over time
 - Still requires recovery/re-execution on misprediction
 - ❑ Alpha 21264 : Initially assume load independent, delay loads found to be dependent
 - ❑ Moshovos et al., “**Dynamic speculation and synchronization of data dependences**,” ISCA 1997.
 - ❑ Chrysos and Emer, “**Memory Dependence Prediction Using Store Sets**,” ISCA 1998.

Memory Disambiguation (II)

- Chrysos and Emer, “Memory Dependence Prediction Using Store Sets,” ISCA 1998.

- Predicting store-load dependencies important for performance
- Simple predictors (based on past history) can achieve most of the potential performance

Data Forwarding Between Stores and Loads

- We cannot update memory out of program order
 - Need to buffer all store and load instructions in instruction window
- Even if we **know** all addresses of past stores when we generate the address of a load, two questions still remain:
 1. How do we check whether or not it is dependent on a store
 2. How do we forward data to the load if it is dependent on a store
- Modern processors use a LQ (load queue) and a SQ for this
 - Can be combined or separate between loads and stores
 - A load searches the SQ after it computes its address. Why?
 - A store searches the LQ after it computes its address. Why?

Out-of-Order Completion of Memory Ops

- When a store instruction finishes execution, it writes its address and data in its reorder buffer entry (or SQ entry)
- When a later load instruction generates its address, it:
 - searches the SQ with its address
 - accesses memory with its address
 - receives the value from the youngest older instruction that wrote to that address (either from ROB or memory)
- This is a complicated “search logic” implemented as a Content Addressable Memory
 - Content is “memory address” (but also need *size* and *age*)
 - Called **store-to-load forwarding logic**

Store-Load Forwarding Complexity

- Content Addressable Search (based on Load Address)
- Range Search (based on Address and Size of both the Load and earlier Stores)
- Age-Based Search (for last written values)
- Load data can come from a combination of multiple places
 - One or more stores in the Store Buffer (SQ)
 - Memory/cache

Agenda for Today & Next Few Lectures

- Single-cycle Microarchitectures
 - Multi-cycle and Microprogrammed Microarchitectures
 - Pipelining
 - Issues in Pipelining: Control & Data Dependence Handling, State Maintenance and Recovery, ...
 - Out-of-Order Execution
 - Other Execution Paradigms
-

Other Approaches to Concurrency (or Instruction Level Parallelism)

Approaches to (Instruction-Level) Concurrency

- Pipelining
- Fine-Grained Multithreading
- Out-of-order Execution
- Dataflow (at the ISA level)
- Superscalar Execution
- VLIW
- SIMD Processing (Vector and array processors, GPUs)
- Decoupled Access Execute
- Systolic Arrays

Review: Data Flow: Exploiting Irregular Parallelism

Recall: OOO Execution: Restricted Dataflow

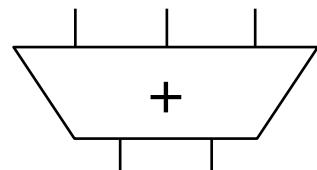

- An out-of-order engine dynamically builds the dataflow graph of a piece of the program
- The dataflow graph is limited to the **instruction window**
 - Instruction window: all decoded but not yet retired instructions
- Can we do it for the whole program?
 - In other words, how can we have a large instruction window?
- Can we do it efficiently with Tomasulo's algorithm?

Recall: State of RAT and RS in Cycle 7

		Cycle	1	2	3	4	5	6	7
MUL	R1, R2	\rightarrow	R3	F	D	E_1	E_2	E_3	E_4
ADD	R3, R4	\rightarrow	R5	F	D	-	-	-	-
ADD	R2, R6	\rightarrow	R7	F	D	E_1	E_2	E_3	
ADD	R8, R9	\rightarrow	R10	F	D	E_1	E_2		
MUL	R7, R10	\rightarrow	R11	F	D	-			
ADD	R5, R11	\rightarrow	R5	F	D

Dataflow graph

Nodes: operations performed by the instruction

Arches: tags in Tomasulo's algorithm

Data Flow Summary

- Availability of data determines order of execution
 - A data flow node fires when its sources are ready
 - Programs represented as data flow graphs (of nodes)
-
- Data Flow at the ISA level has not been (as) successful
-
- Data Flow implementations at the microarchitecture level (while preserving Von Neumann semantics) have been very successful
 - Out of order execution is the prime example

Pure Data Flow Advantages/Disadvantages

■ Advantages

- ❑ Very good at exploiting **irregular parallelism**
- ❑ Only real dependencies constrain processing
- ❑ More parallelism can be exposed than Von Neumann model

■ Disadvantages

- ❑ No precise state semantics
 - Debugging very difficult
 - Interrupt/exception handling is difficult (what is precise state semantics?)
- ❑ Too much parallelism? (Parallelism control needed)
- ❑ High bookkeeping overhead (tag matching, data storage)
- ❑ ...

Approaches to (Instruction-Level) Concurrency

- Pipelining
- Fine-Grained Multithreading
- Out-of-order Execution
- Dataflow (at the ISA level)
- Superscalar Execution
- VLIW
- SIMD Processing (Vector and array processors, GPUs)
- Decoupled Access Execute
- Systolic Arrays

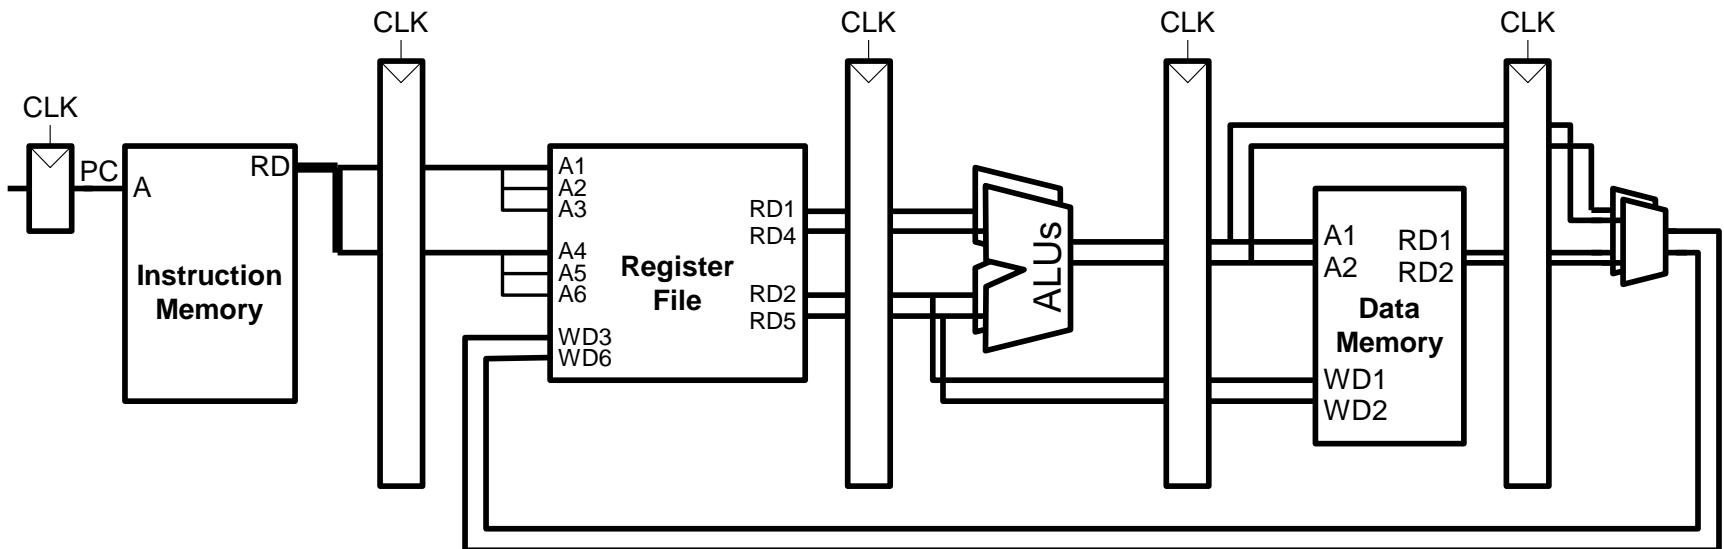

Superscalar Execution

Superscalar Execution

- Idea: Fetch, decode, execute, retire **multiple instructions per cycle**
 - N-wide superscalar → N instructions per cycle
- Need to add the hardware resources for doing so
- Hardware performs the dependence checking between concurrently-fetched instructions
- Superscalar execution and out-of-order execution are orthogonal concepts
 - Can have all four combinations of processors:
[in-order, out-of-order] × [scalar, superscalar]

In-Order Superscalar Processor Example

- Multiple copies of datapath: Can fetch/decode/execute multiple instructions per cycle
- Dependencies make it tricky to issue multiple instructions at once

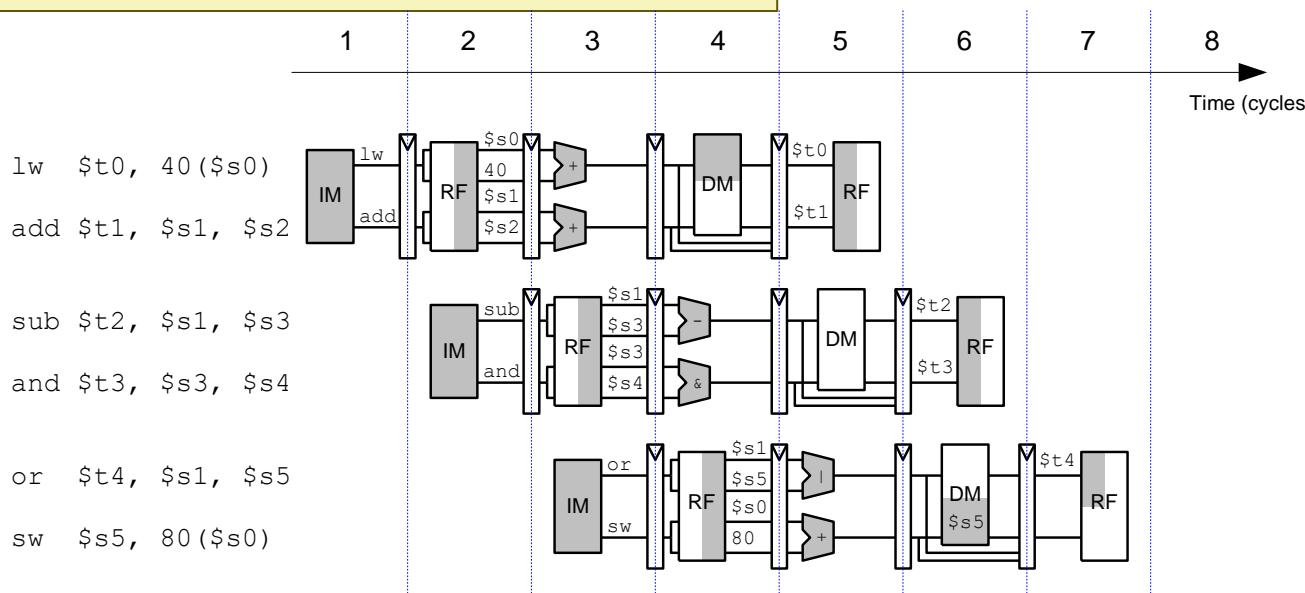

Here: Ideal IPC = 2

In-Order Superscalar Performance Example

```
lw $t0, 40($s0)
add $t1, $s1, $s2
sub $t2, $s1, $s3
and $t3, $s3, $s4
or $t4, $s1, $s5
sw $s5, 80($s0)
```

Ideal IPC = 2

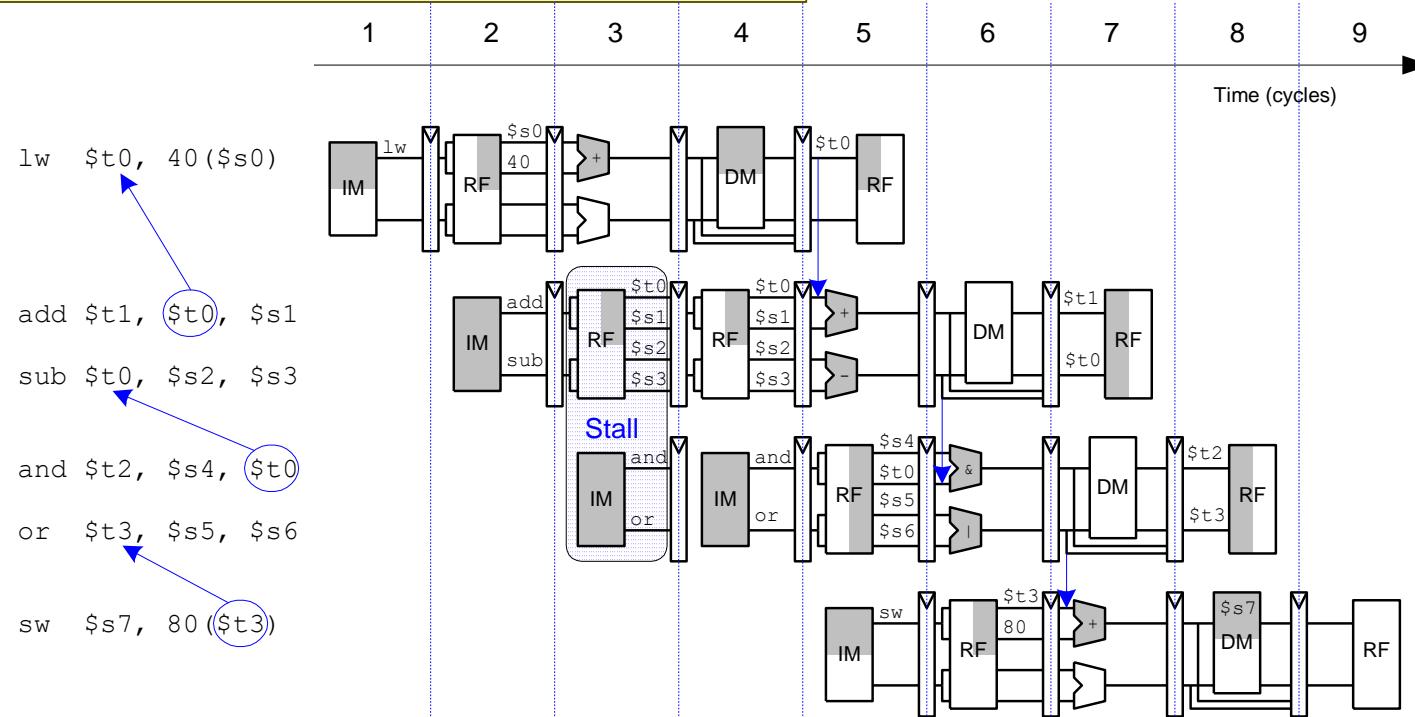

Actual IPC = 2 (6 instructions issued in 3 cycles)

Superscalar Performance with Dependencies

```
lw $t0, 40($s0)
add $t1, $t0, $s1
sub $t0, $s2, $s3
and $t2, $s4, $t0
or $t3, $s5, $s6
sw $s7, 80($t3)
```

Ideal IPC = 2

Actual IPC = 1.2 (6 instructions issued in 5 cycles)

Superscalar Execution Tradeoffs

- Advantages
 - Higher IPC (instructions per cycle)

- Disadvantages
 - Higher complexity for dependency checking
 - Require checking within a pipeline stage
 - Renaming becomes more complex in an OoO processor
 - More hardware resources needed
