Memory (Programmer's View)

Ideal Memory

- Zero access time (latency)
- Infinite capacity
- Zero cost
- Infinite bandwidth (to support multiple accesses in parallel)

Abstraction: Virtual vs. Physical Memory

- **Programmer** sees **virtual memory**
 - Can assume the memory is “infinite”
 - Reality: **Physical memory** size is much smaller than what the programmer assumes
 - **The system** (system software + hardware, cooperatively) maps **virtual memory addresses** to **physical memory**
 - The system automatically manages the physical memory space **transparently to the programmer**
- + Programmer does not need to know the physical size of memory nor manage it → A small physical memory can appear as a huge one to the programmer → Life is easier for the programmer
- More complex system software and architecture

A classic example of the programmer/(micro)architect tradeoff

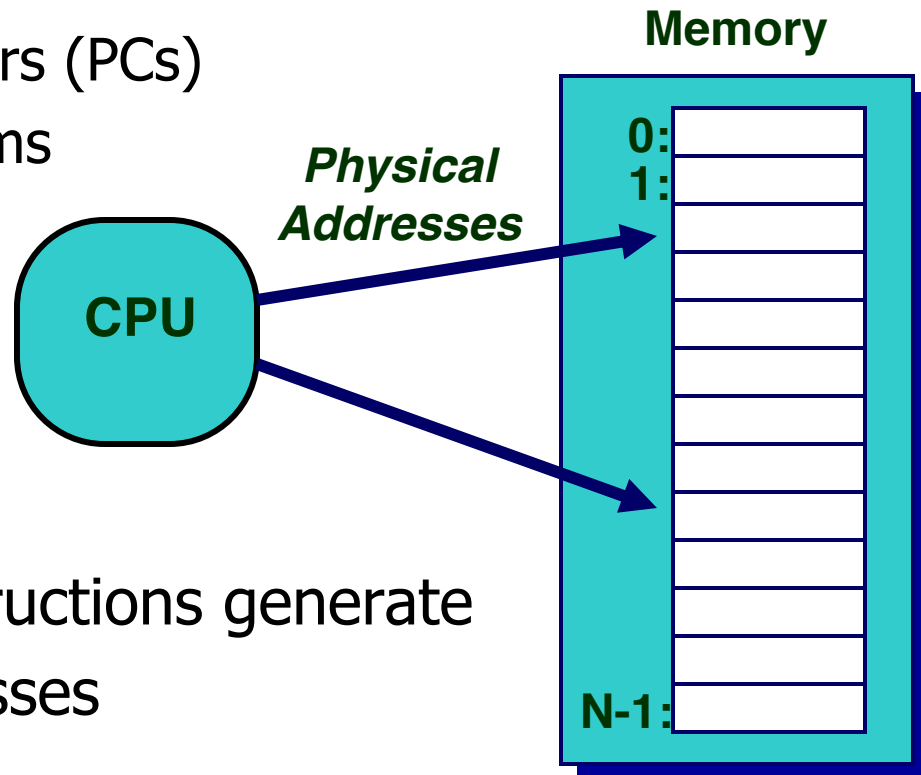

Benefits of Automatic Management of Memory

- Programmer does not deal with physical addresses
- Each process has its own mapping from virtual→physical addresses

- Enables
 - ❑ Code and data to be located anywhere in physical memory
(relocation)
 - ❑ Isolation/separation of code and data of different processes in physical memory
(protection and isolation)
 - ❑ Code and data sharing between multiple processes
(sharing)

A System with Physical Memory Only

- Examples:
 - ❑ most Cray machines
 - ❑ early personal computers (PCs)
 - ❑ many embedded systems

CPU's load or store instructions generate physical memory addresses

The Problem

- Physical memory is of limited size (cost)
 - What if you need more?
 - Should the programmer be concerned about the size of code/data blocks fitting physical memory?
 - Should the programmer manage data movement from disk to physical memory?
 - Should the programmer ensure two processes (different programs) do not use the same physical memory?
- Also, ISA can have an address space greater than the physical memory size
 - E.g., a 64-bit address space with byte addressability
 - What if you do not have enough physical memory?

Difficulties of Direct Physical Addressing

- Programmer needs to manage physical memory space
 - Inconvenient & hard
 - Harder when you have multiple processes
- Difficult to support code and data relocation
 - Addresses are directly specified in the program
- Difficult to support multiple processes
 - Protection and isolation between multiple processes
 - Sharing of physical memory space
- Difficult to support data/code sharing across processes

Virtual Memory

- Idea: Give the programmer the illusion of a large address space while having a small physical memory
 - So that the programmer does not worry about managing physical memory
- Programmer can assume he/she has “infinite” amount of physical memory
- Hardware and software cooperatively and automatically manage the physical memory space to provide the illusion
 - Illusion is maintained for each independent process

Basic Mechanism

- Indirection (in addressing)
- Address generated by each instruction in a program is a “virtual address”
 - i.e., it is not the physical address used to address main memory
 - called “linear address” in x86
- An “address translation” mechanism maps this address to a “physical address”
 - called “real address” in x86
 - Address translation mechanism can be implemented in hardware and software together

A System with Virtual Memory (Page based)

- **Address Translation:** The hardware converts virtual addresses into physical addresses via an OS-managed lookup table (page table)

Virtual Pages, Physical Frames

- Virtual address space divided into pages
- Physical address space divided into frames
- A virtual page is mapped to
 - A physical frame, if the page is in physical memory
 - A location in disk, otherwise
- If an accessed virtual page is not in memory, but on disk
 - Virtual memory system brings the page into a physical frame and adjusts the mapping → this is called demand paging
- Page table is the table that stores the mapping of virtual pages to physical frames

Physical Memory as a Cache

- In other words...
- Physical memory is a cache for pages stored on disk
 - In fact, it is a fully associative cache in modern systems (a virtual page can potentially be mapped to any physical frame)
- Similar caching issues exist as we have covered earlier:
 - Placement: where and how to place/find a page in cache?
 - Replacement: what page to remove to make room in cache?
 - Granularity of management: large, small, uniform pages?
 - Write policy: what do we do about writes? Write back?

Cache/Virtual Memory Analogues

Cache	Virtual Memory
Block	Page
Block Size	Page Size
Block Offset	Page Offset
Miss	Page Fault
Tag	Virtual Page Number

Virtual Memory Definitions

- **Page size**: amount of memory transferred from hard disk to DRAM at once
- **Address translation**: determining the physical address from the virtual address
- **Page table**: lookup table used to translate virtual addresses to physical addresses (and find where the associated data is)

Virtual and Physical Addresses

© 2007 Elsevier, Inc. All rights reserved

- Most accesses hit in physical memory
- But programs see the large capacity of virtual memory

Address Translation

Virtual Address

Physical Address

Virtual Memory Example

- System:

- Virtual memory size: 2 GB = 2^{31} bytes
- Physical memory size: 128 MB = 2^{27} bytes
- Page size: 4 KB = 2^{12} bytes

Virtual Memory Example

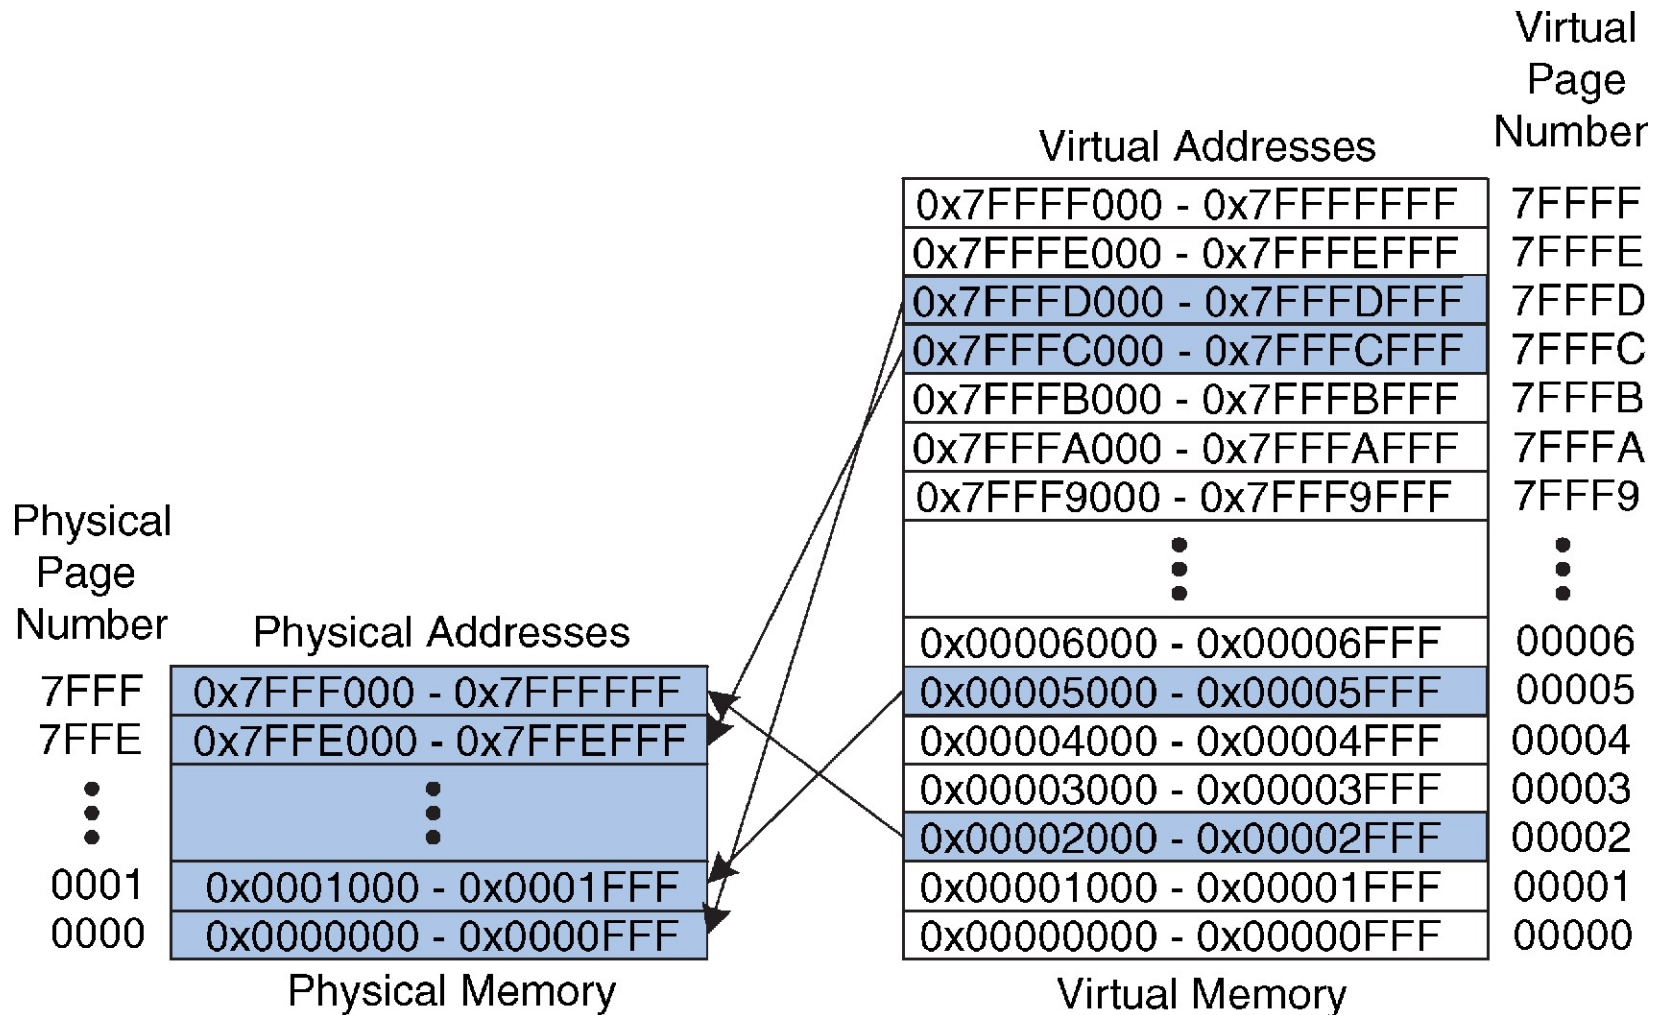

■ System:

- ❑ Virtual memory size: 2 GB = 2^{31} bytes
- ❑ Physical memory size: 128 MB = 2^{27} bytes
- ❑ Page size: 4 KB = 2^{12} bytes

■ Organization:

- ❑ Virtual address: **31** bits
- ❑ Physical address: **27** bits
- ❑ Page offset: **12** bits
- ❑ # Virtual pages = $2^{31}/2^{12} = 2^{19}$ (VPN = 19 bits)
- ❑ # Physical pages = $2^{27}/2^{12} = 2^{15}$ (PPN = 15 bits)

Virtual Memory Example

How Do We Translate Addresses?

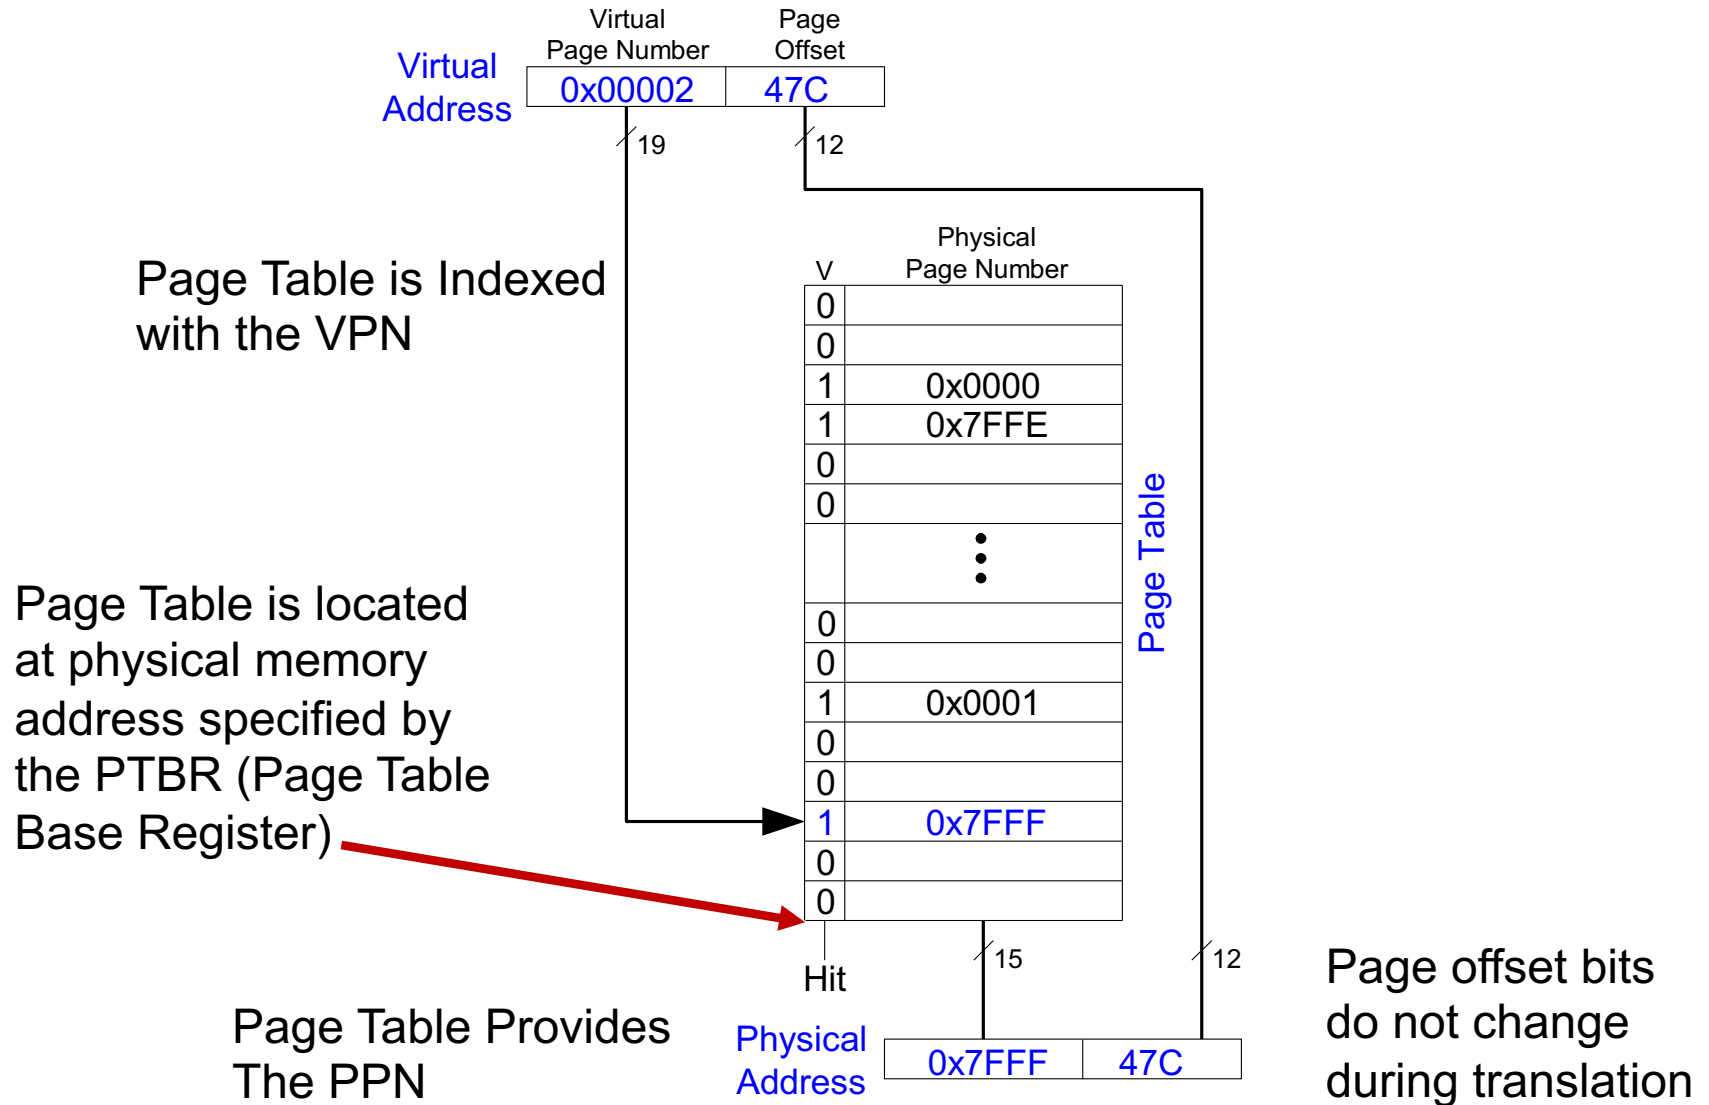

- **Page table**

- Has entry for each virtual page

- Each **page table entry** has:

- **Valid bit**: whether the virtual page is located in physical memory (if not, it must be fetched from the hard disk)
- **Physical page number**: where the virtual page is located in physical memory
- (Replacement policy, dirty bits)

Page Table Address Translation Example

Page Table Address Translation Example 1

- What is the physical address of virtual address 0x5F20?
- We first need to find the page table entry containing the translation for the corresponding VPN
- Look up the PTE at the address
 - $PTBR + VPN * PTE\text{-}size$

Page Table Address Translation Example 2

- What is the physical address of virtual address 0x73E0?
 - VPN = 7
 - Entry 7 in page table is invalid, so the page is not in physical memory
 - The virtual page must be swapped into physical memory from disk

Issue: Page Table Size

- Suppose 64-bit VA and 40-bit PA, how large is the page table?
 - **2^{52} entries x ~4 bytes $\approx 2^{54}$ bytes**
and that is for just one process!
and the process may not be using the entire VM space!

Page Table Challenges

- Challenge 1: **Page table is large**
 - at least part of it needs to be located in physical memory
 - solution: multi-level (hierarchical) page tables
- Challenge 2: **Each instruction fetch or load/store requires at least two memory accesses:**
 1. one for address translation (page table read)
 2. one to access data with the physical address (after translation)
- Two memory accesses to service an instruction fetch or load/store greatly degrades execution time
 - Unless we are clever... → speed up the translation...

Translation Lookaside Buffer (TLB)

- Idea: Cache the page table entries (PTEs) in a hardware structure in the processor to speed up address translation
- Translation lookaside buffer (TLB)
 - Small cache of most recently used translations (PTEs)
 - Reduces number of memory accesses required for *most* instruction fetches and loads/stores to only one

Translation Lookaside Buffer (TLB)

- Page table accesses have a lot of temporal locality
 - ❑ Data accesses have temporal and spatial locality
 - ❑ Large page size (say 4KB, 8KB, or even 1-2GB)
 - ❑ Consecutive instructions and loads/stores are likely to access same page
- TLB
 - ❑ Small: accessed in ~ 1 cycle
 - ❑ Typically 16 - 512 entries
 - ❑ High associativity
 - ❑ $> 95\text{-}99\%$ hit rates typical (depends on workload)
 - ❑ Reduces number of memory accesses for most instruction fetches and loads/stores to only one

Example Two-Entry TLB

Virtual Memory Support and Examples

Supporting Virtual Memory

- Virtual memory **requires both HW+SW support**
 - Page Table is in memory
 - Can be cached in special hardware structures called Translation Lookaside Buffers (TLBs)
- The hardware component is called the **MMU** (memory management unit)
 - Includes Page Table Base Register(s), TLBs, page walkers
- **It is the job of the software** to leverage the MMU to
 - Populate page tables, decide what to replace in physical memory
 - Change the Page Table Register on context switch (to use the running thread's page table)
 - Handle page faults and ensure correct mapping

Address Translation

- How to obtain the physical address from a virtual address?
- Page size specified by the ISA
 - VAX: 512 bytes
 - Today: 4KB, 8KB, 2GB, ... (small and large pages mixed together)
 - Trade-offs? (remember cache lectures)
- Page Table contains an entry for each virtual page
 - Called Page Table Entry (PTE)
 - What is in a PTE?

What Is in a Page Table Entry (PTE)?

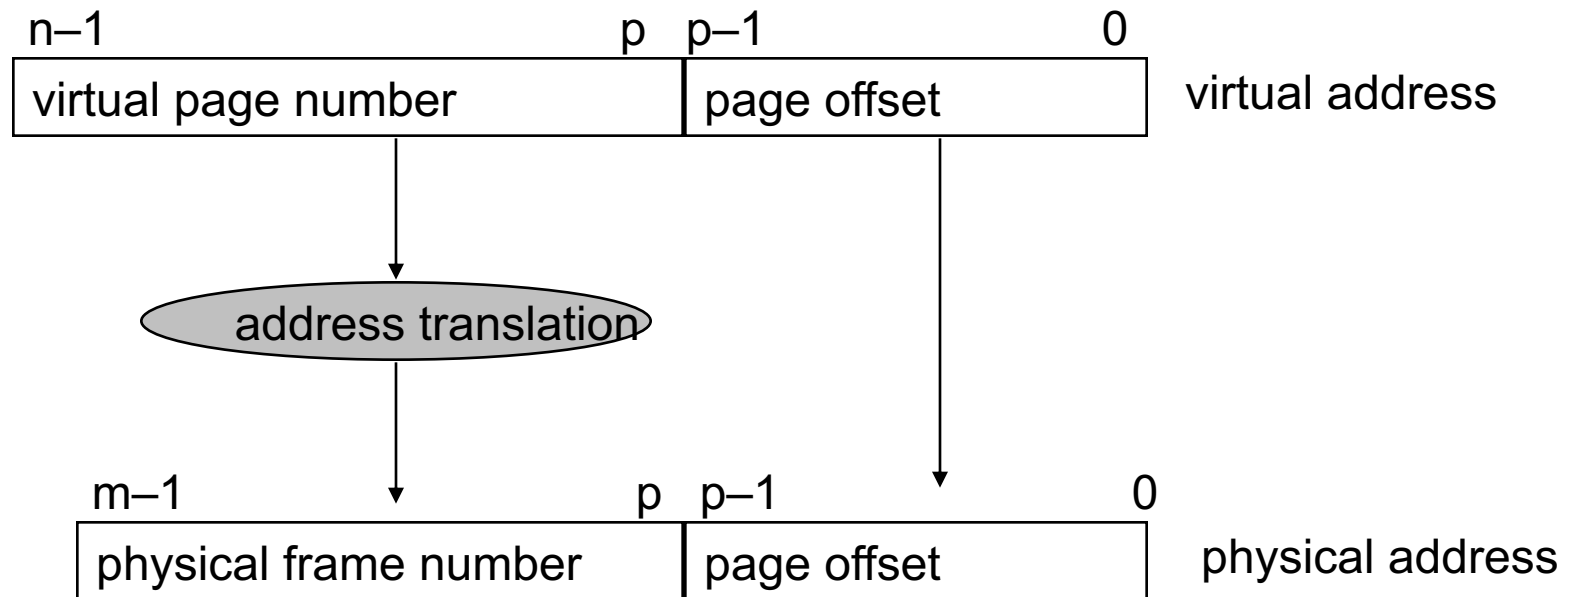

- Page table is the “tag store” for the physical memory data store
 - ❑ A mapping table between virtual memory and physical memory
- PTE is the “tag store entry” for a virtual page in memory
 - ❑ Need a **valid** bit → to indicate validity/presence in physical memory
 - ❑ Need **tag** bits (PFN) → to support translation
 - ❑ Need bits to support **replacement**
 - ❑ Need a **dirty** bit to support “write back caching”
 - ❑ Need **protection bits** to enable access control and protection

Address Translation (I)

■ Parameters

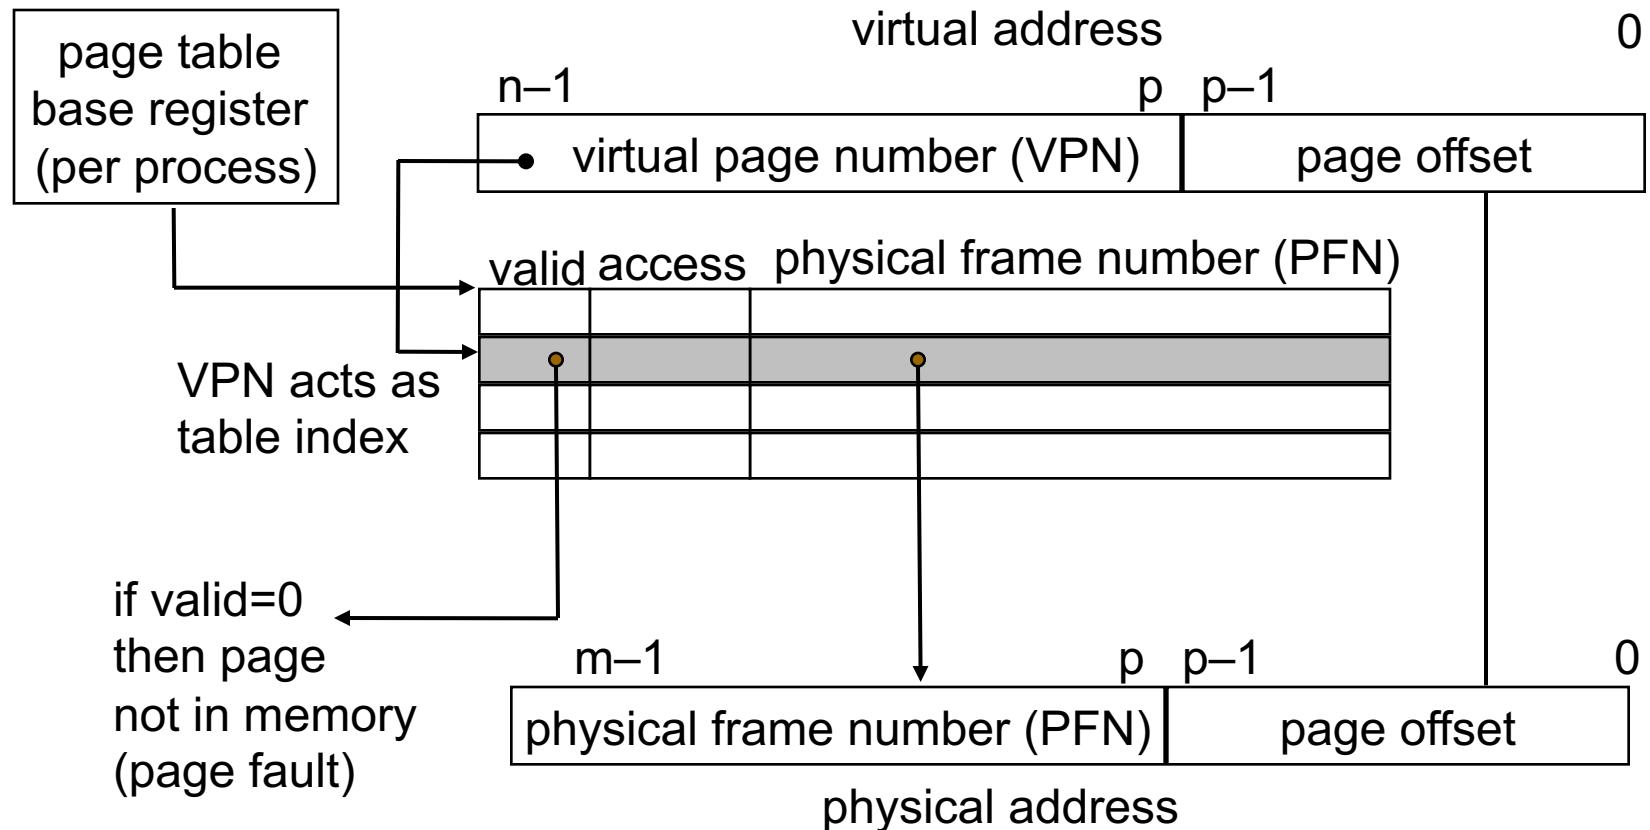

- ❑ $P = 2^p =$ page size (bytes).
- ❑ $N = 2^n =$ Virtual-address limit
- ❑ $M = 2^m =$ Physical-address limit

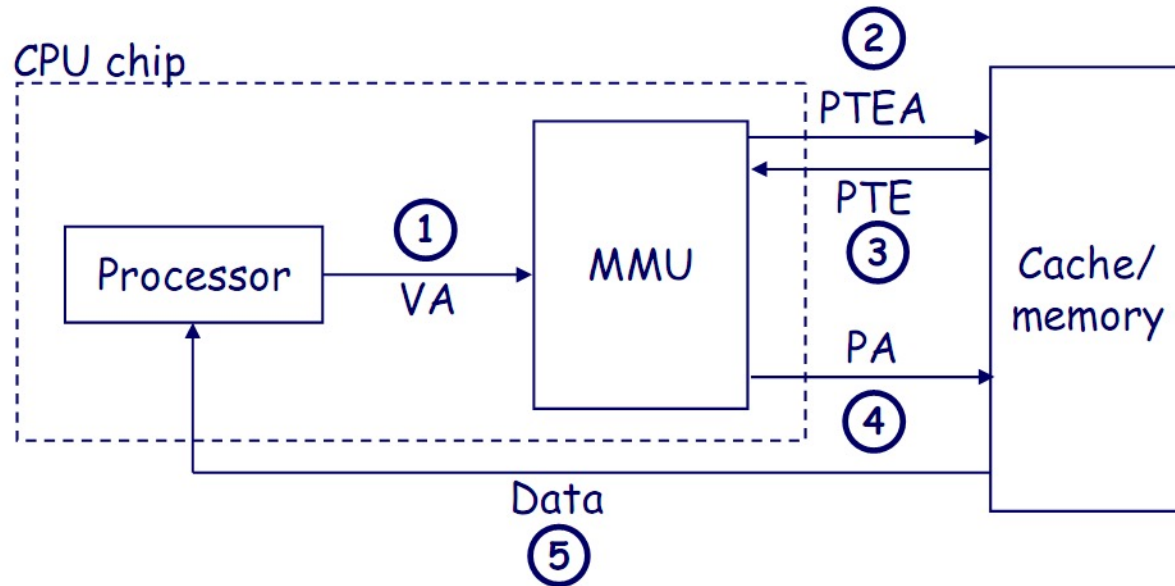

Page offset bits don't change as a result of translation

Address Translation (II)

- Separate (set of) page table(s) per process
- VPN forms index into page table (points to a page table entry)
- Page Table Entry (PTE) provides information about page

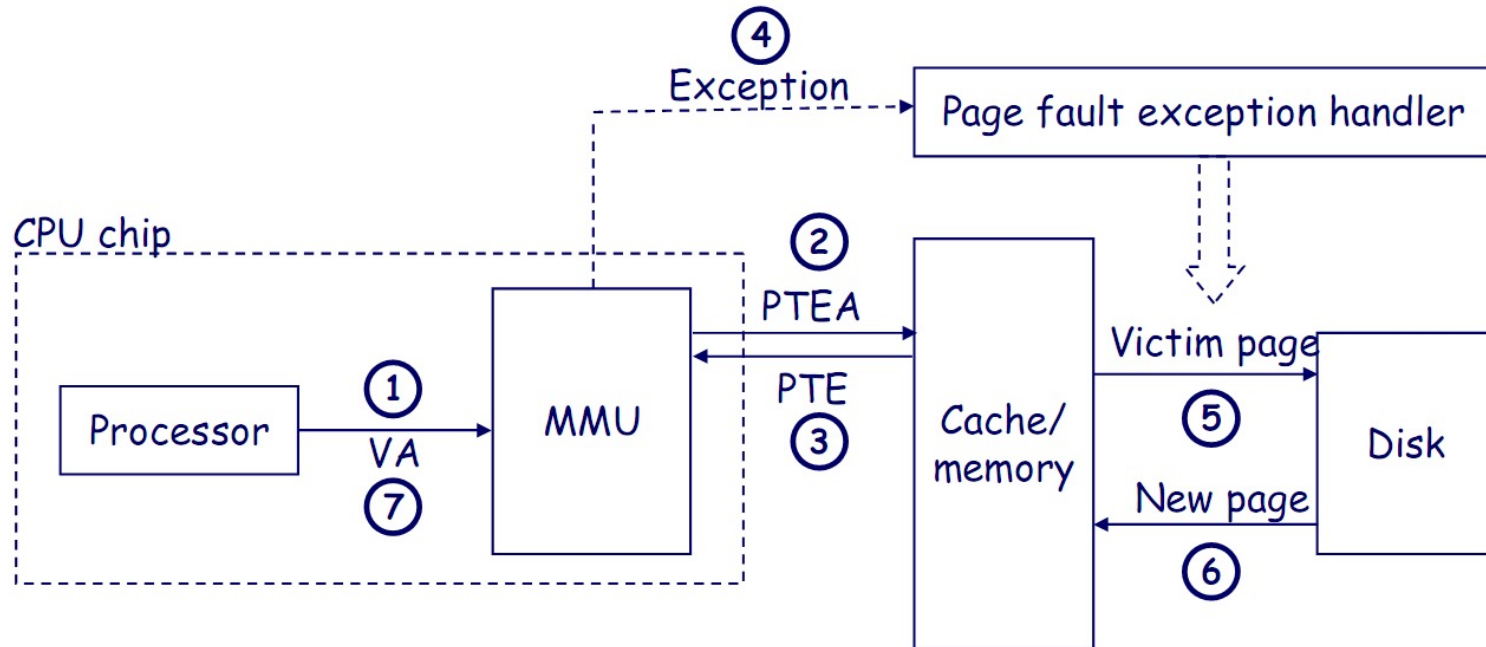

Address Translation: Page Hit

- 1) Processor sends virtual address to MMU
- 2-3) MMU fetches PTE from page table in memory
- 4) MMU sends physical address to L1 cache
- 5) L1 cache sends data word to processor

Address Translation: Page Fault

- 1) Processor sends virtual address to MMU
- 2-3) MMU fetches PTE from page table in memory
- 4) Valid bit is zero, so MMU triggers page fault exception
- 5) Handler identifies victim, and if dirty pages it out to disk
- 6) Handler pages in new page and updates PTE in memory
- 7) Handler returns to original process, restarting faulting instruction.

Page Fault (“A Miss in Physical Memory”)

- If a page is not in physical memory but disk
 - ❑ Page table entry indicates virtual page not in memory
 - ❑ Access to such a page triggers a page fault exception
 - ❑ OS trap handler invoked to move data from disk into memory
 - Other processes can continue executing
 - OS has full control over placement

Before fault

After fault

Servicing a Page Fault

- (1) Processor signals controller
 - Read block of length P starting at disk address X and store starting at memory address Y
- (2) Read occurs
 - Direct Memory Access (DMA)
 - Under control of I/O controller
- (3) Controller signals completion
 - Interrupt processor
 - OS resumes suspended process

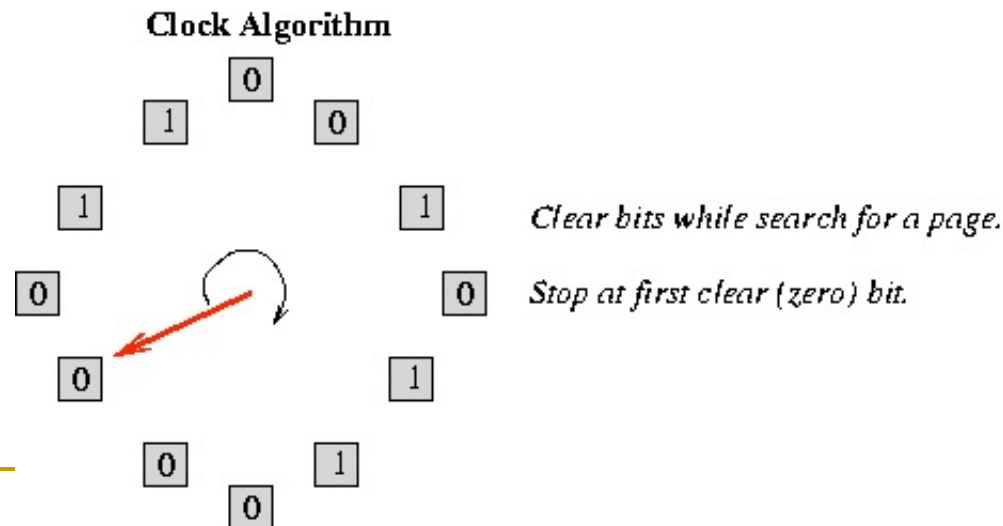

Page Replacement Algorithms

- If physical memory is full (i.e., list of free physical pages is empty), which physical frame to replace on a page fault?
- Is True LRU feasible?
 - 4GB memory, 4KB pages, how many possibilities of ordering?
- Modern systems use approximations of LRU
 - E.g., the CLOCK algorithm
- And, more sophisticated algorithms to take into account “frequency” of use
 - E.g., the ARC algorithm
 - Megiddo and Modha, “ARC: A Self-Tuning, Low Overhead Replacement Cache,” FAST 2003.

CLOCK Page Replacement Algorithm

- Keep a **circular list of physical frames** in memory (OS does)
- Keep a **pointer** (hand) to the last-examined frame in the list
- When a page is accessed, set the R bit in the PTE
- When a frame needs to be replaced, replace the first frame that has the reference (R) bit not set, traversing the circular list starting from the pointer (hand) clockwise
 - ❑ During traversal, clear the R bits of examined frames
 - ❑ Set the hand pointer to the next frame in the list

Cache versus Page Replacement

- Physical memory (DRAM) is a cache for disk
 - Managed by system software via the virtual memory subsystem
- Page replacement is similar to cache replacement
- Page table is the “tag store” for physical memory data store
- What is the difference?
 - Required speed of access to cache vs. physical memory
 - Number of blocks in a cache vs. physical memory
 - “Tolerable” amount of time to find a replacement candidate (disk versus memory access latency)
 - Role of hardware versus software

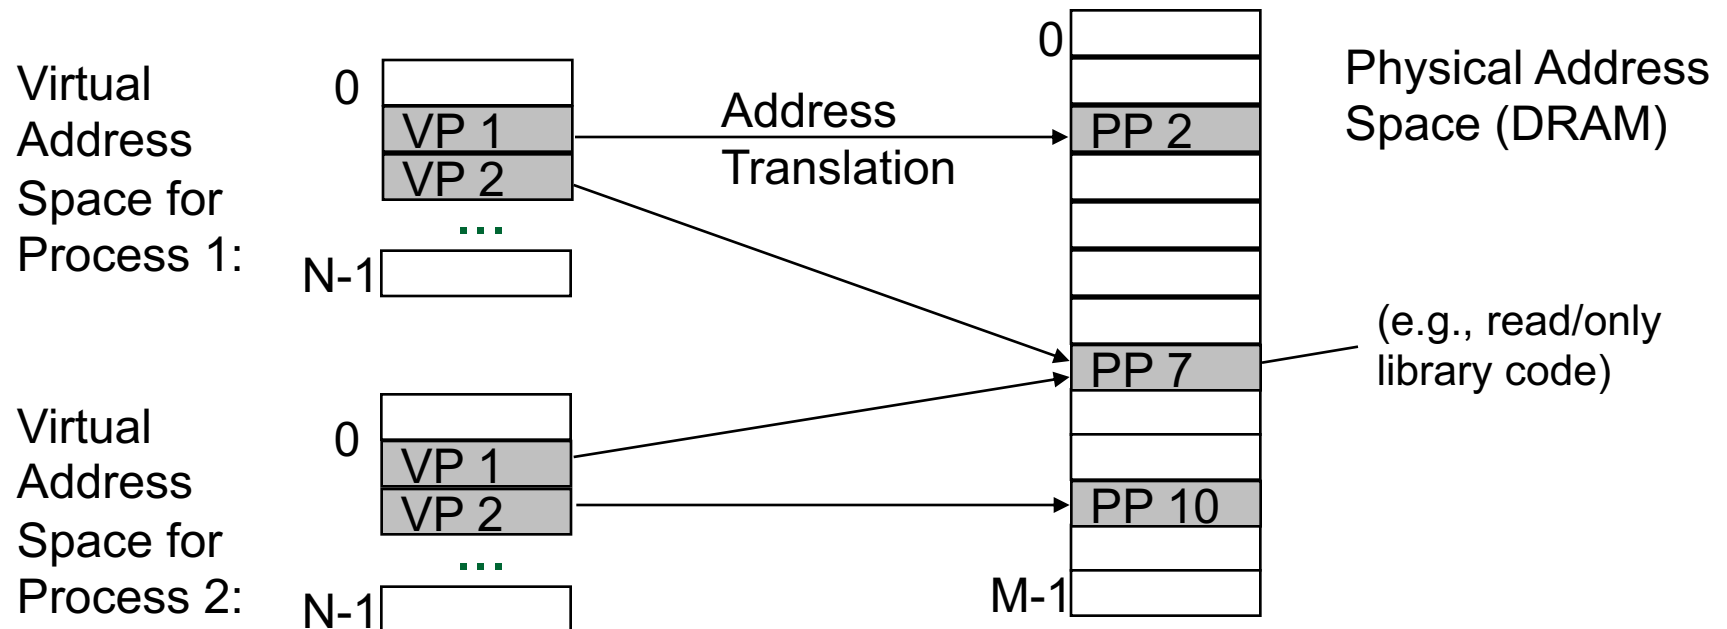

Memory Protection

Memory Protection

- Multiple programs (*processes*) run at once
 - Each process has its own page table
 - Each process can use entire virtual address space without worrying about where other programs are
- A process can only access physical pages mapped in its page table – cannot overwrite memory of another process
 - Provides protection and isolation between processes
 - Enables access control mechanisms per page

Page Table is Per Process

- Each process has its own virtual address space
 - Full address space for each program
 - Simplifies memory allocation, sharing, linking and loading.

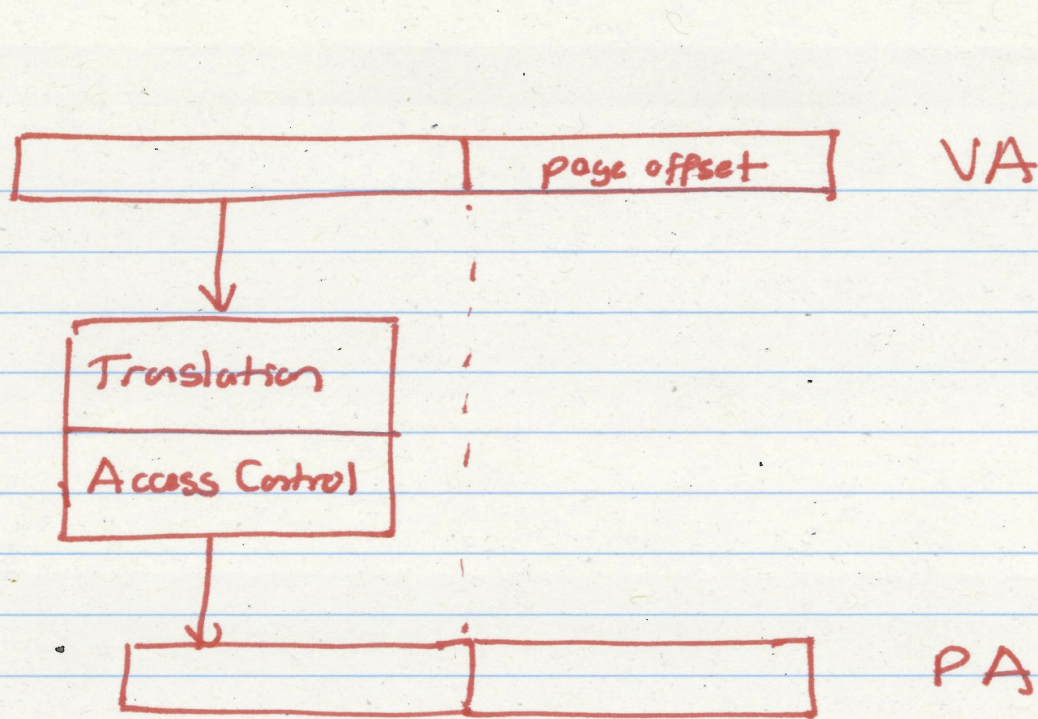

Access Protection/Control via Virtual Memory

Page-Level Access Control (Protection)

- Not every process is allowed to access every page
 - E.g., may need supervisor level privilege to access system pages
 - Idea: Store access control information on a page basis in the process's page table
 - Enforce access control at the same time as translation
- Virtual memory system serves two functions today
- Address translation (for illusion of large physical memory)
 - Access control (protection)

Two Functions of Virtual Memory

Virtual
Memory

Two Functions
Today

1. Translation
2. Access control (protection)

PTE contains access control bits associated with the virtual page.

VM as a Tool for Memory Access Protection

- Extend Page Table Entries (PTEs) with permission bits
- Check bits on each access and during a page fault
 - If violated, generate exception (Access Protection exception)

Food for Thought: What If?

- Your hardware is unreliable and someone can flip the access protection bits
 - such that a user-level program can gain supervisor-level access (i.e., access to all data on the system)
 - by flipping the access control bit from user to supervisor!
- Can this happen?

Exploiting the DRAM rowhammer bug to gain kernel privileges

RowHammer Security Attack Example

- “Rowhammer” is a problem with some recent DRAM devices in which repeatedly accessing a row of memory can cause bit flips in adjacent rows (Kim et al., ISCA 2014).
 - Flipping Bits in Memory Without Accessing Them: An Experimental Study of DRAM Disturbance Errors (Kim et al., ISCA 2014)
- We tested a selection of laptops and found that a subset of them exhibited the problem.
- We built two working privilege escalation exploits that use this effect.
 - Exploiting the DRAM rowhammer bug to gain kernel privileges (Seaborn+, 2015)
- One exploit uses rowhammer-induced bit flips to gain kernel privileges on x86-64 Linux when run as an unprivileged userland process.
- When run on a machine vulnerable to the rowhammer problem, the process was able to induce bit flips in page table entries (PTEs).
- It was able to use this to gain write access to its own page table, and hence gain read-write access to all of physical memory.

Takeaway and Food for Thought

- If hardware is unreliable, higher-level security and protection mechanisms (as in virtual memory) may be compromised
- The root of security and trust is at the very low levels...
 - in the hardware itself
 - RowHammer, Spectre, Meltdown are recent key examples...
- What should we assume the hardware provides?
- How do we keep hardware reliable?
- How do we design secure hardware?
- How do we design secure hardware with high performance, high energy efficiency, low cost, convenient programming?

Plenty of exciting and highly-relevant research questions

Some Issues in Virtual Memory

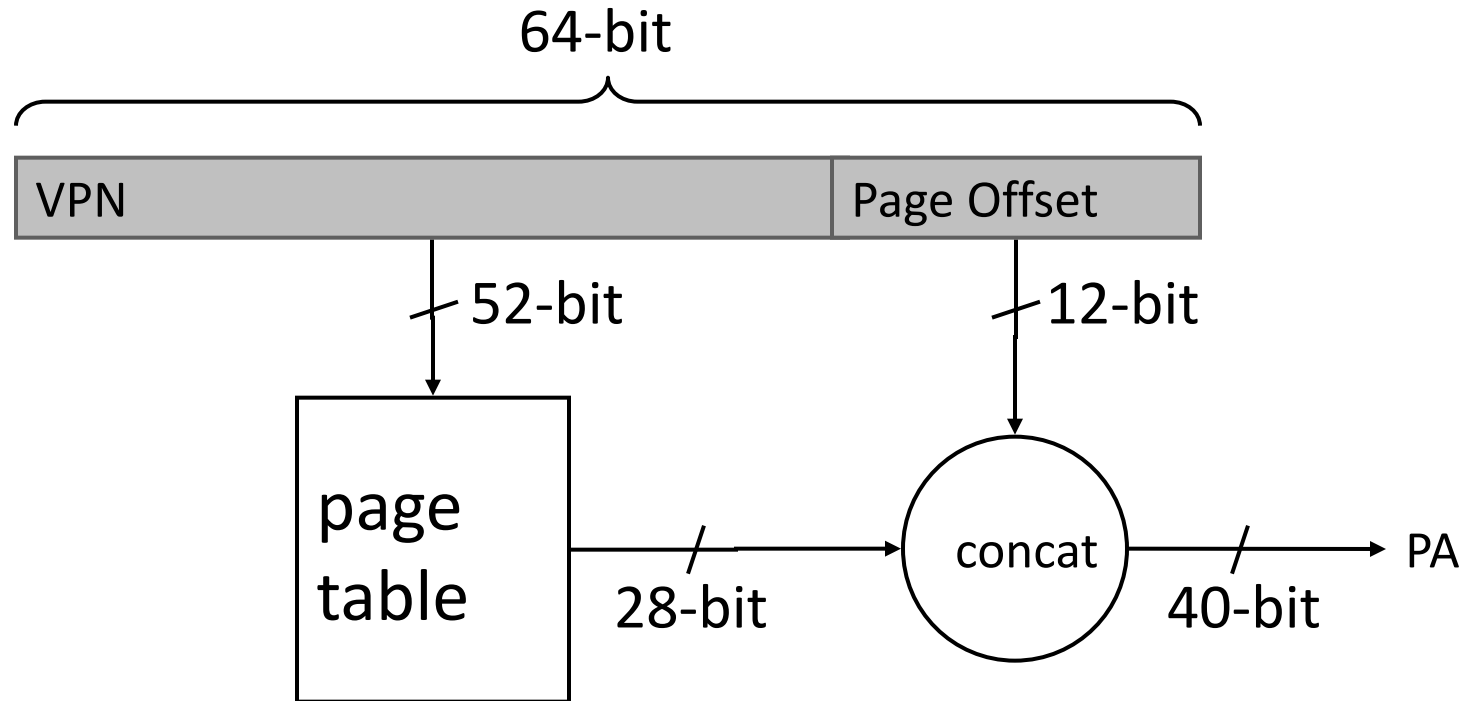

Three Major Issues

1. How large is the page table and how do we store and access it?
 2. How can we speed up translation & access control check?
 3. When do we do the translation in relation to cache access?
- There are many other issues we will not cover in detail
 - What happens on a context switch?
 - How can you handle multiple page sizes?
 - ...

Virtual Memory Issue I

- How large is the page table?
- Where do we store it?
 - In hardware?
 - In physical memory? (Where is the PTBR?)
 - In virtual memory? (Where is the PTBR?)
- How can we store it efficiently without requiring physical memory that can store all page tables?
 - Idea: multi-level page tables
 - Only the first-level page table has to be in physical memory
 - Remaining levels are in virtual memory (but get cached in physical memory when accessed)

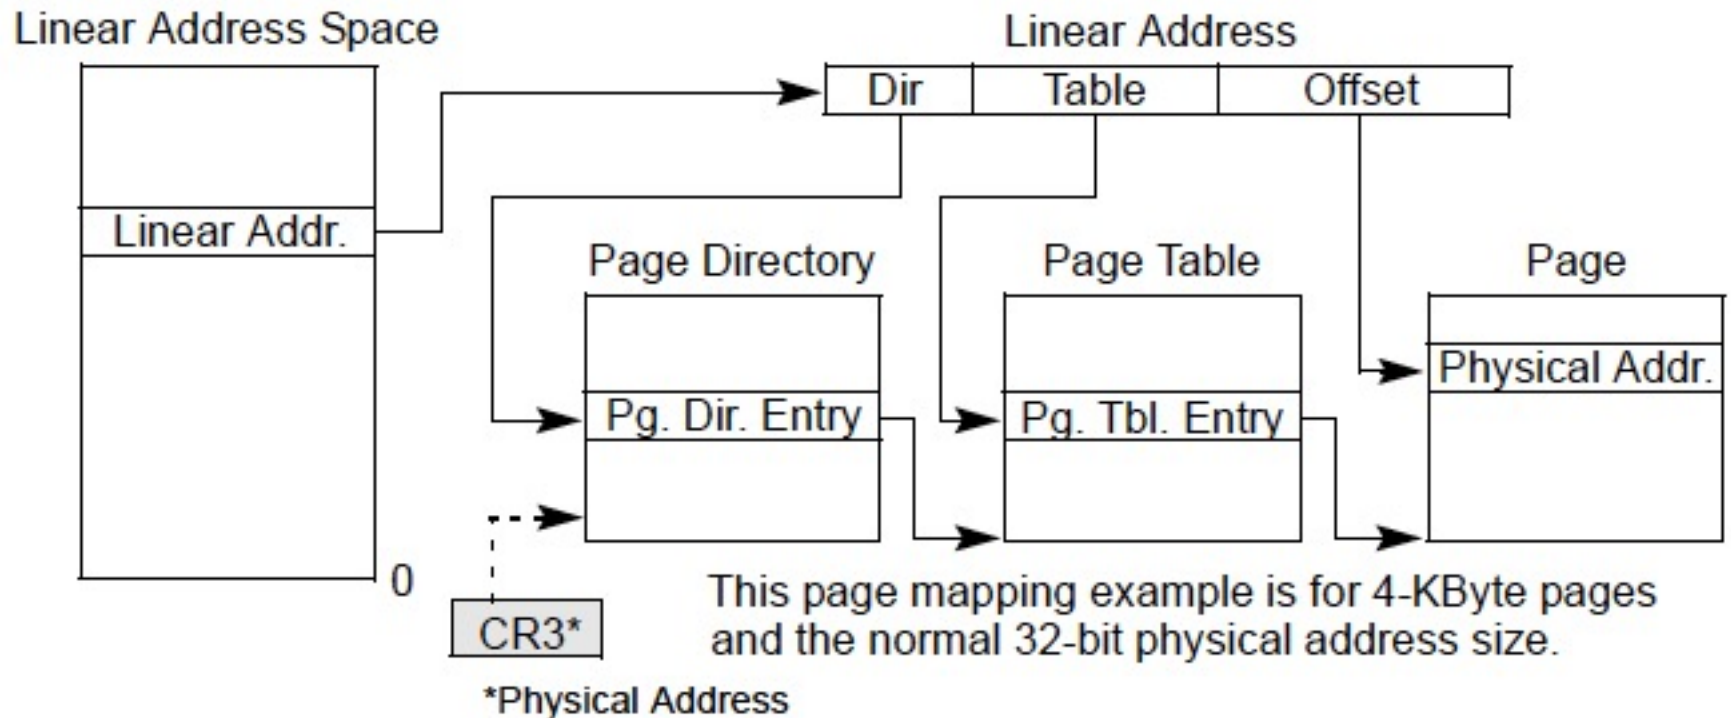

Issue: Page Table Size

- Suppose 64-bit VA and 40-bit PA, how large is the page table?
 - **2^{52} entries x ~4 bytes $\approx 2^{54}$ bytes**
and that is for just one process!
and the process may not be using the entire VM space!

Solution: Multi-Level Page Tables

Example from the x86 architecture

Page Table Access

- How do we access the Page Table?
- Page Table Base Register (CR3 in x86)
- Page Table Limit Register
- If VPN is out of the bounds (exceeds PTLR) then the process did not allocate the virtual page → access control exception
- Page Table Base Register is part of a process's context
 - Just like PC, status registers, general purpose registers
 - Needs to be loaded when the process is context-switched in

Four-level Paging in x86

Figure 4-8. Linear-Address Translation to a 4-KByte Page using IA-32e Paging

Four-level Paging and Extended Physical Address Space in x86

A logical processor uses IA-32e paging if $CR0.PG = 1$, $CR4.PAE = 1$, and $IA32_EFER.LME = 1$. With IA-32e paging, linear addresses are translated using a hierarchy of in-memory paging structures located using the contents of CR3. IA-32e paging translates 48-bit linear addresses to 52-bit physical addresses.¹ Although 52 bits corresponds to 4 PBytes, linear addresses are limited to 48 bits; at most 256 TBytes of linear-address space may be accessed at any given time.

IA-32e paging uses a hierarchy of paging structures to produce a translation for a linear address. CR3 is used to locate the first paging-structure, the PML4 table. Use of CR3 with IA-32e paging depends on whether process-context identifiers (PCIDs) have been enabled by setting CR4.PCIDE:

Virtual Memory Summary

Virtual Memory Summary

- Virtual memory gives the illusion of “infinite” capacity
- A subset of virtual pages are located in physical memory
- A page table maps virtual pages to physical pages – this is called address translation
- A TLB speeds up address translation
- Multi-level page tables keep the page table size in check
- Using different page tables for different programs provides memory protection

Virtual Memory: Parting Thoughts

- VM is one of the most successful examples of
 - ❑ architectural support for programmers
 - ❑ how to partition work between hardware and software
 - ❑ hardware/software cooperation
 - ❑ programmer/architect tradeoff
- Going forward: How does virtual memory scale into the future? Four key trends:
 - ❑ Increasing, huge physical memory sizes
 - ❑ Hybrid physical memory systems (DRAM + NVM + SSD)
 - ❑ Many accelerators in the system addressing physical memory
 - ❑ Virtualized systems (hypervisors, software virtualization, local and remote memories)

Four-level Paging in x86

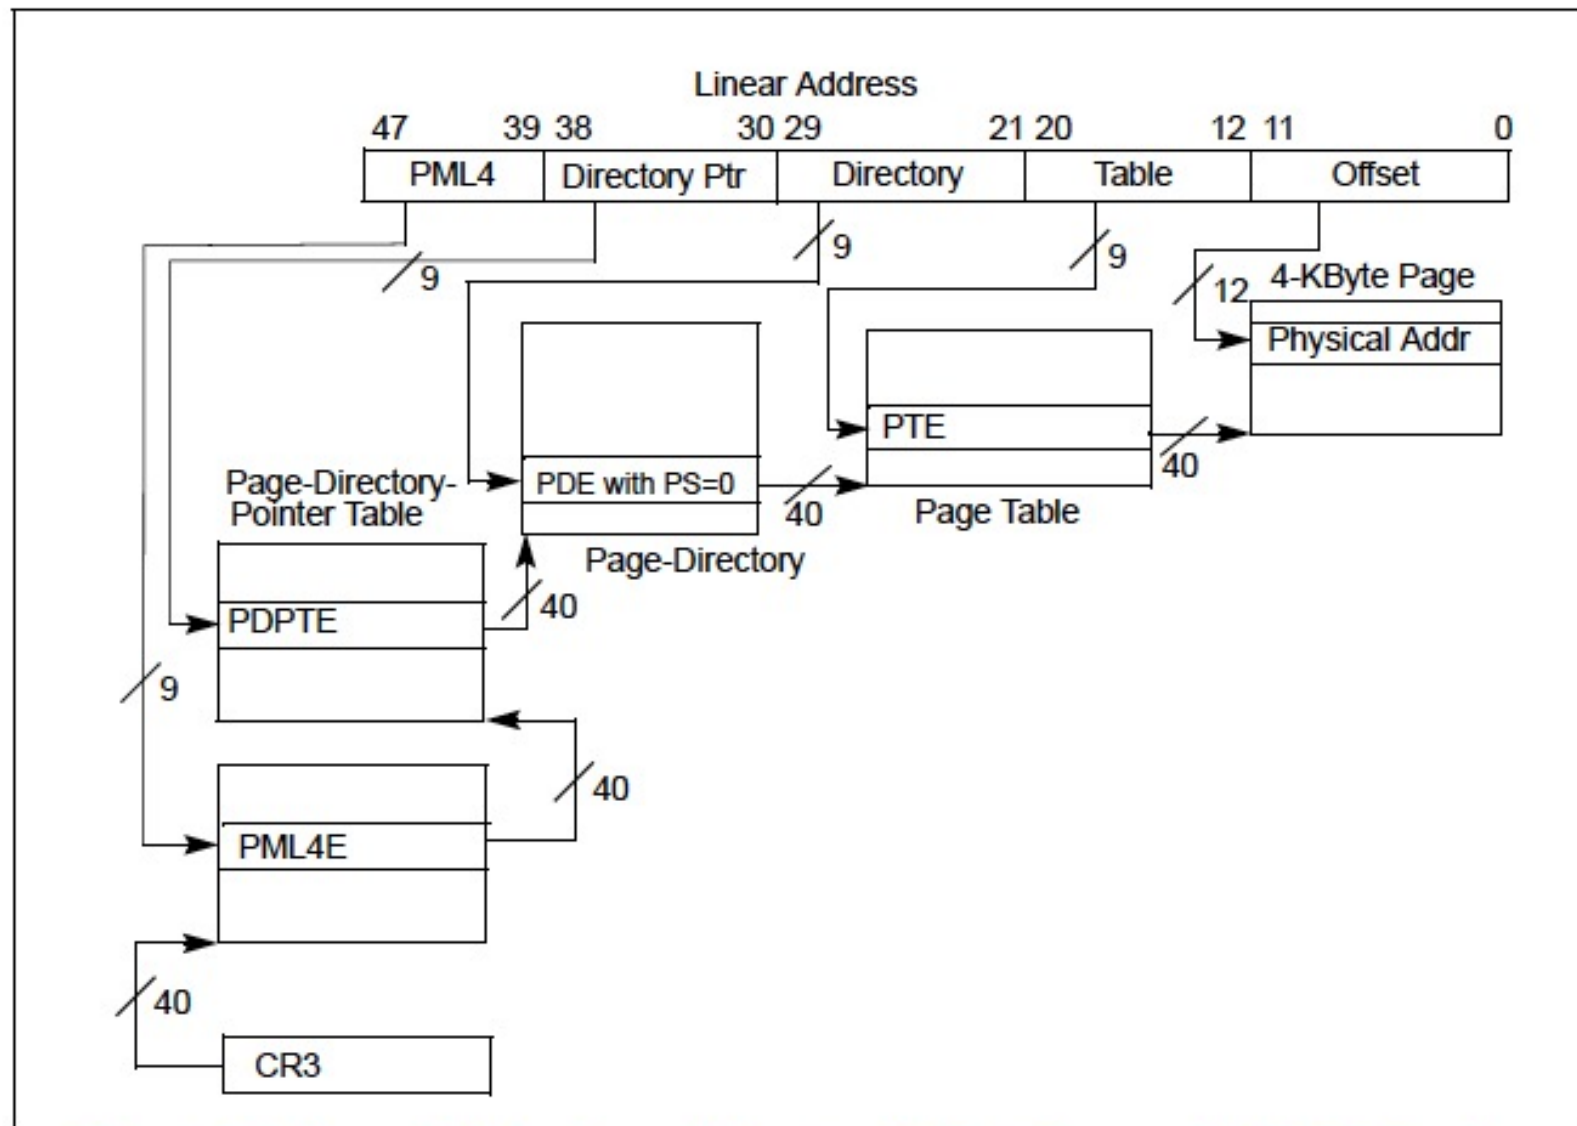

Figure 4-8. Linear-Address Translation to a 4-KByte Page using IA-32e Paging

Four-level Paging and Extended Physical Address Space in x86

A logical processor uses IA-32e paging if $CR0.PG = 1$, $CR4.PAE = 1$, and $IA32_EFER.LME = 1$. With IA-32e paging, linear addresses are translated using a hierarchy of in-memory paging structures located using the contents of CR3. IA-32e paging translates 48-bit linear addresses to 52-bit physical addresses.¹ Although 52 bits corresponds to 4 PBytes, linear addresses are limited to 48 bits; at most 256 TBytes of linear-address space may be accessed at any given time.

IA-32e paging uses a hierarchy of paging structures to produce a translation for a linear address. CR3 is used to locate the first paging-structure, the PML4 table. Use of CR3 with IA-32e paging depends on whether process-context identifiers (PCIDs) have been enabled by setting CR4.PCIDE:

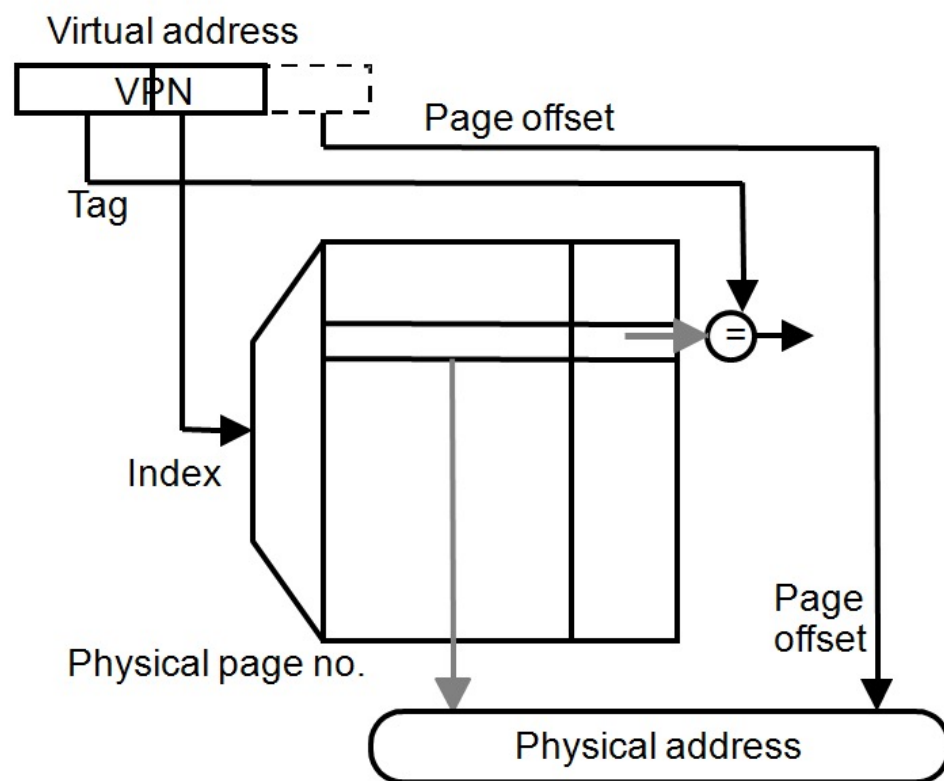

Virtual Memory Issue II

- How fast is the address translation?
 - How can we make it fast?
- Idea: Use a hardware structure that caches PTEs → Translation lookaside buffer
- What should be done on a TLB miss?
 - What TLB entry to replace?
 - Who handles the TLB miss? HW vs. SW?
- What should be done on a page fault?
 - What virtual page to replace from physical memory?
 - Who handles the page fault? HW vs. SW?

Speeding up Translation with a TLB

- Essentially a cache of recent address translations
 - Avoids going to the page table on every reference
- **Index** = lower bits of VPN (virtual page #)
- **Tag** = unused bits of VPN + process ID
- **Data** = a page-table entry
- **Status** = valid, dirty

The usual cache design choices (placement, replacement policy, multi-level, etc.) apply here too.

Handling TLB Misses

- The TLB is small; it cannot hold all PTEs
 - Some translations will inevitably miss in the TLB
 - Must access memory to find the appropriate PTE
 - Called **walking** the page directory/table
 - Large performance penalty
 - Who handles TLB misses? Hardware or software?
-

Handling TLB Misses (II)

- Approach #1. **Hardware-Managed** (e.g., x86)
 - The hardware does the **page walk**
 - The hardware fetches the PTE and inserts it into the TLB
 - If the TLB is full, the entry **replaces** another entry
 - Done transparently to system software

 - Approach #2. **Software-Managed** (e.g., MIPS)
 - The hardware raises an exception
 - The operating system does the **page walk**
 - The operating system fetches the PTE
 - The operating system inserts/evicts entries in the TLB
-

Handling TLB Misses (III)

■ Hardware-Managed TLB

- ❑ Pro: No exception on TLB miss. Instruction just stalls
- ❑ Pro: Independent instructions may continue
- ❑ Pro: No extra instructions/data brought into caches.
- ❑ Con: Page directory/table organization is etched into the system: OS has little flexibility in deciding these

■ Software-Managed TLB

- ❑ Pro: The OS can define page table organization
 - ❑ Pro: More sophisticated TLB replacement policies are possible
 - ❑ Con: Need to generate an exception → performance overhead due to pipeline flush, exception handler execution, extra instructions brought to caches
-

Virtual Memory Issue III

- When do we do the address translation?
 - Before or after accessing the L1 cache?

Virtual Memory and Cache Interaction

Address Translation and Caching

- When do we do the address translation?
 - Before or after accessing the L1 cache?
- In other words, is the cache virtually addressed or physically addressed?
 - Virtual versus physical cache
- What are the issues with a virtually addressed cache?
- **Synonym problem:**
 - Two different virtual addresses can map to the same physical address → same physical address can be present in multiple locations in the cache → can lead to inconsistency in data

Homonyms and Synonyms

- **Homonym: Same VA can map to two different PAs**
 - Why?
 - VA is in different processes
- **Synonym: Different VAs can map to the same PA**
 - Why?
 - Different pages can share the same physical frame within or across processes
 - Reasons: shared libraries, shared data, copy-on-write pages within the same process, ...
- Do homonyms and synonyms create problems when we have a cache?
 - Is the cache virtually or physically addressed?

Cache-VM Interaction

physical cache

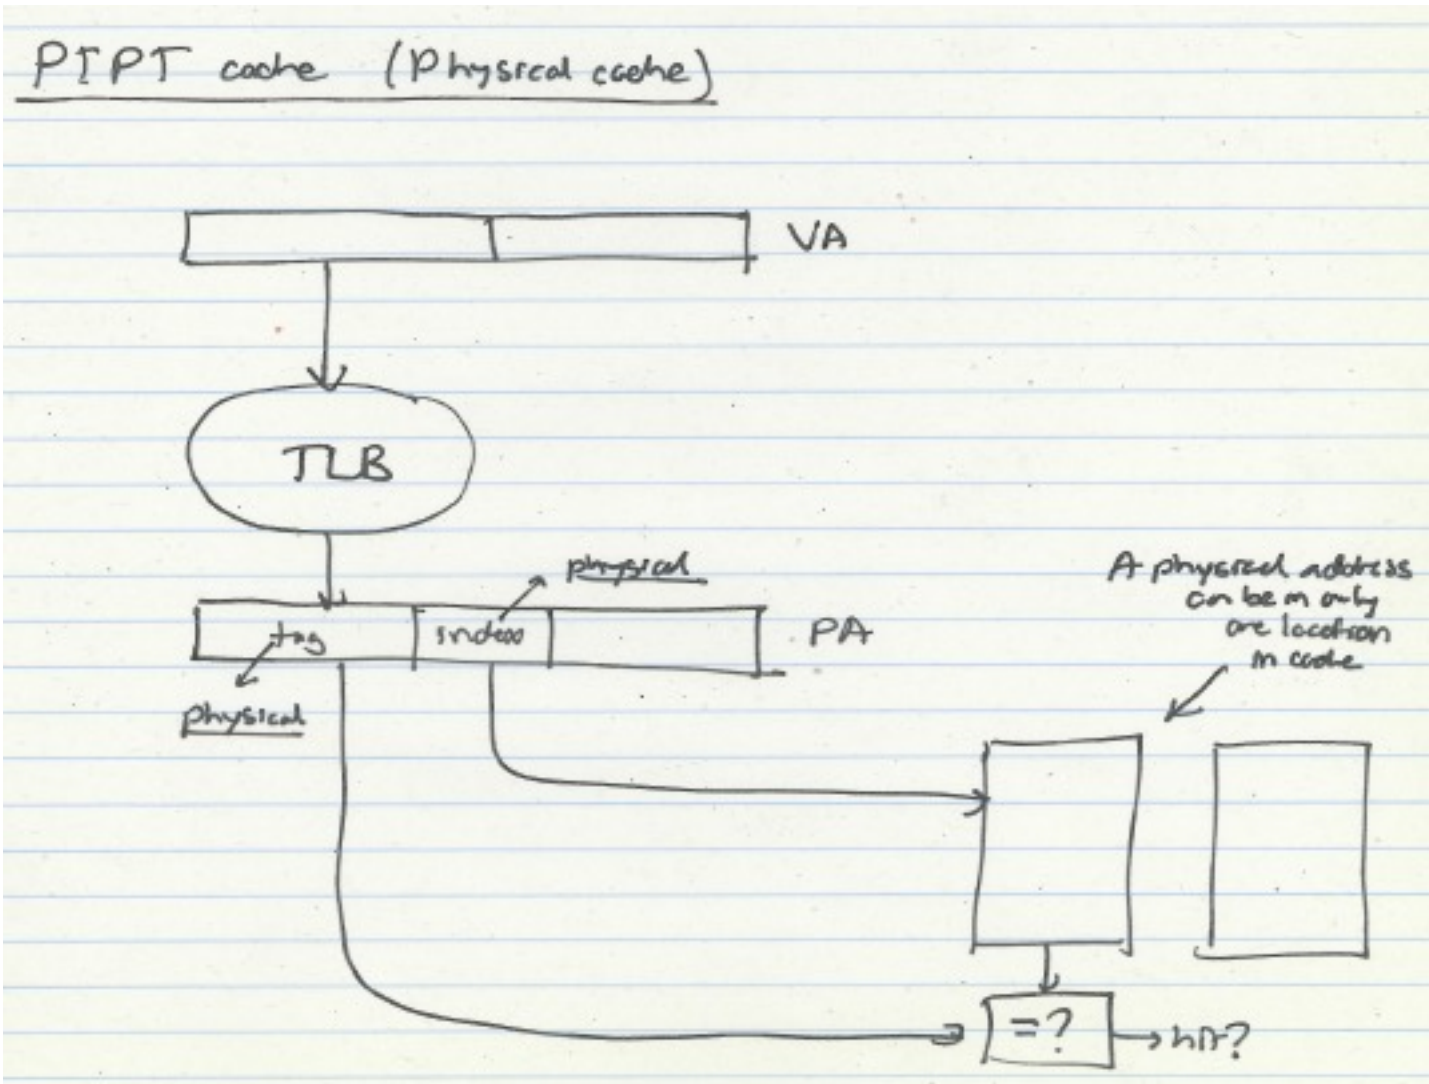

virtual (L1) cache

virtual-physical cache¹³⁴

Physical Cache

Virtual Cache

Virtual-Physical Cache

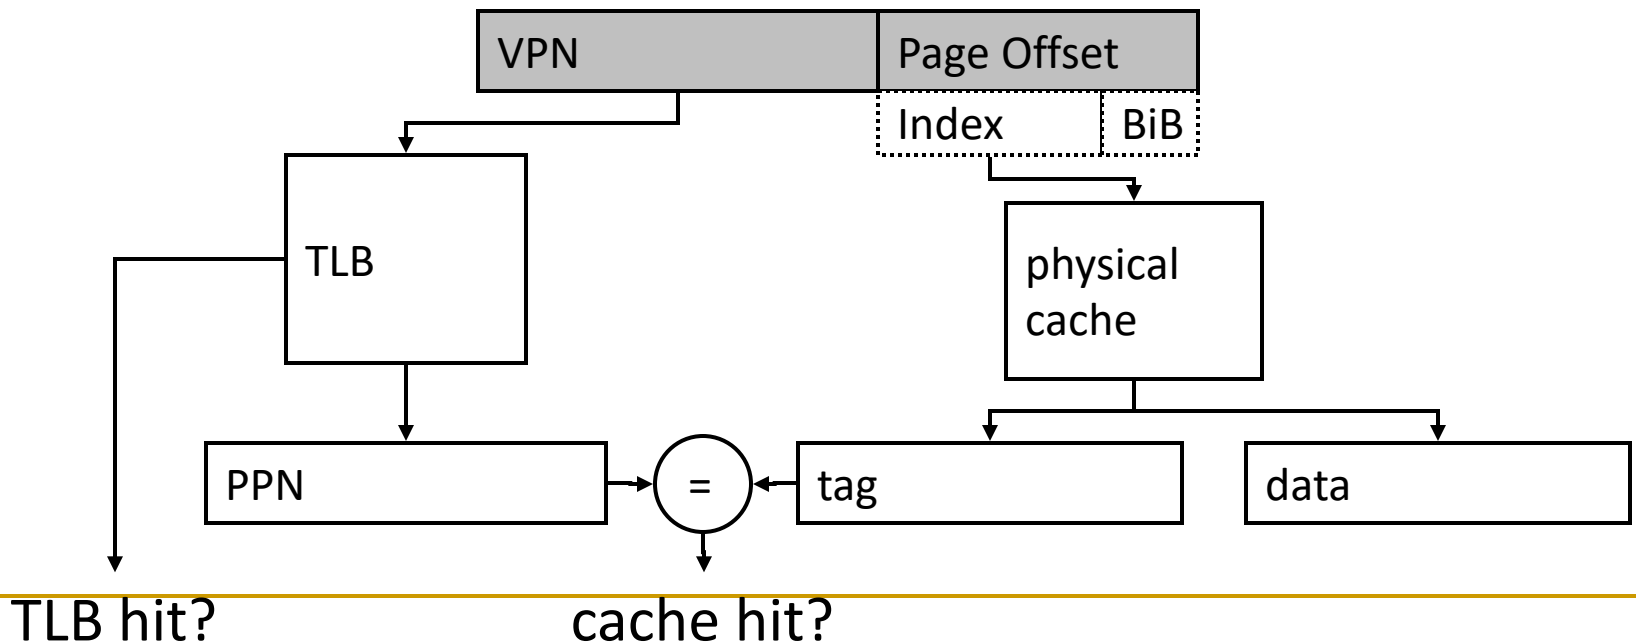

VIPT cache

Where can the same physical address be in the cache?

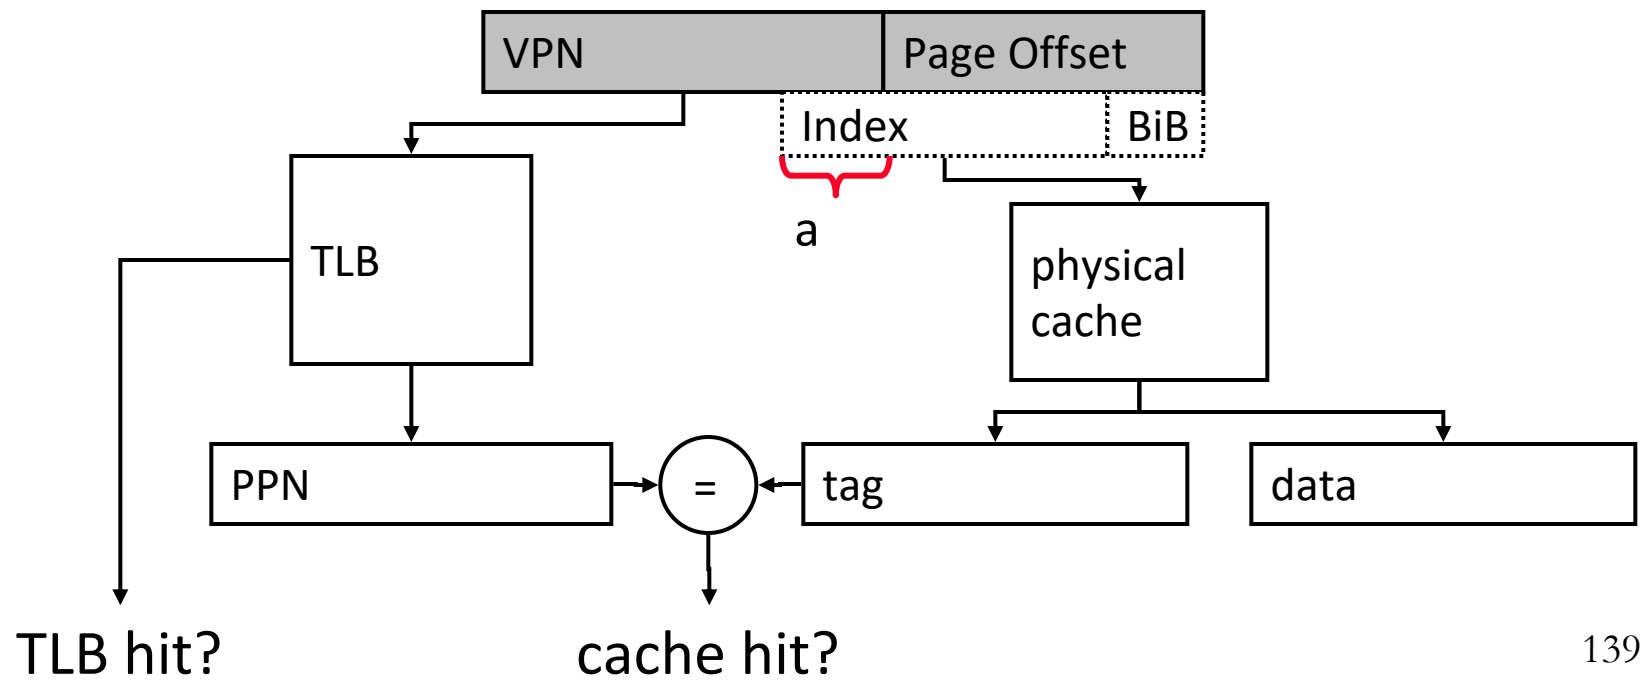

Virtually-Indexed Physically-Tagged

- If $C \leq (\text{page_size} \times \text{associativity})$, the cache index bits come only from page offset (same in VA and PA)
- If both cache and TLB are on chip
 - index both arrays concurrently using VA bits
 - check cache tag (physical) against TLB output at the end

Virtually-Indexed Physically-Tagged

- If $C > (\text{page_size} \times \text{associativity})$, the cache index bits include VPN
⇒ Synonyms can cause problems
 - The same physical address can exist in two locations
- Solutions?

Some Solutions to the Synonym Problem

- Limit cache size to (page size times associativity)
 - get index from page offset
- On a write to a block, search all possible indices that can contain the same physical block, and update/invalidate
 - Used in Alpha 21264, MIPS R10K
- Restrict page placement in OS
 - make sure $\text{index}(\text{VA}) = \text{index}(\text{PA})$
 - Called page coloring
 - Used in many SPARC processors

An Exercise (I)

We have a byte-addressable toy computer that has a physical address space of 512 bytes. The computer uses a simple, one-level virtual memory system. The page table is always in physical memory. The page size is specified as 8 bytes and the virtual address space is 2 KB.

Part A.

i. (1 point)

How many bits of each virtual address is the virtual page number?

ii. (1 point)

How many bits of each physical address is the physical frame number?

We would like to add a 128-byte *write-through* cache to enhance the performance of this computer. However, we would like the cache access and address translation to be performed simultaneously. In other words, we would like to index our cache using a virtual address, but do the tag comparison using the physical addresses (virtually-indexed physically-tagged). The cache we would like to add is direct-mapped, and has a block size of 2 bytes. The replacement policy is LRU. Answer the following questions:

iii. (1 point)

How many bits of a virtual address are used to determine which byte in a block is accessed?

iv. (2 point)

How many bits of a virtual address are used to index into the cache? Which bits exactly?

v. (1 point)

How many bits of the virtual page number are used to index into the cache?

What is the size of the tag store in bits? Show your work.

Part B.

Suppose we have two processes sharing our toy computer. These processes share some portion of the physical memory. Some of the virtual page-physical frame mappings of each process are given below:

PROCESS 0	
Virtual Page	Physical Frame
Page 0	Frame 0
Page 3	Frame 7
Page 7	Frame 1
Page 15	Frame 3

PROCESS 1	
Virtual Page	Physical Frame
Page 0	Frame 4
Page 1	Frame 5
Page 7	Frame 3
Page 11	Frame 2

vii. (2 points)

Give a complete physical address whose data can exist in two different locations in the cache.

viii. (3 points)

Give the indexes of those two different locations in the cache.

An Exercise (Concluded)

ix. (5 points)

We do not want the same physical address stored in two different locations in the 128-byte cache. We can prevent this by increasing the associativity of our virtually-indexed physically-tagged cache. What is the minimum associativity required?

x. (4 points)

Assume we would like to use a direct-mapped cache. Describe a solution that ensures that the same physical address is never stored in two different locations in the 128-byte cache.

Some System Software Tasks for VM

- Keeping track of which physical frames are free
- Allocating free physical frames to virtual pages
- Page replacement policy
 - When no physical frame is free, what should be removed?
- Sharing pages between processes
- Copy-on-write optimization
- Page-flip optimization
