Some Issues in Virtual Memory
Three Major Issues in Virtual Memory

1. How large is the page table and how do we store and access it?

2. How can we speed up translation & access control check?

3. When do we do the translation in relation to cache access?

- There are many other issues we will not cover in detail
  - What happens on a context switch?
  - How can you handle multiple page sizes?
  - ...
Virtual Memory Issue I

- How large is the page table?

- Where do we store it?
  - In hardware?
  - In physical memory? (Where is the PTBR?)
  - In virtual memory? (Where is the PTBR?)

- How can we store it efficiently without requiring physical memory that can store all page tables?
  - Idea: multi-level page tables
  - Only the first-level page table has to be in physical memory
  - Remaining levels are in virtual memory (but get cached in physical memory when accessed)
Recall: Solution: Multi-Level Page Tables

Example from the x86 architecture

This page mapping example is for 4-KByte pages and the normal 32-bit physical address size.
Page Table Access

- How do we access the Page Table?

- Page Table Base Register (CR3 in x86)
- Page Table Limit Register

- If VPN is out of the bounds (exceeds PTLR) then the process did not allocate the virtual page → access control exception

- Page Table Base Register is part of a process’s context
  - Just like PC, status registers, general purpose registers
  - Needs to be loaded when the process is context-switched in
More on x86 Page Tables (I): Small Pages

Figure 4-2. Linear-Address Translation to a 4-KByte Page using 32-Bit Paging
Figure 4-3. Linear-Address Translation to a 4-MByte Page using 32-Bit Paging
Figure 4-4 gives a summary of the formats of CR3 and the paging-structure entries with 32-bit paging. For the paging structure entries, it identifies separately the format of entries that map pages, those that reference other paging structures, and those that do neither because they are “not present”; bit 0 (P) and bit 7 (PS) are highlighted because they determine how such an entry is used.

<table>

X86-64 Page Table: Accessing 1GB pages

Figure 4-10. Linear-Address Translation to a 1-GByte Page using 4-Level Paging
Three Major Issues in Virtual Memory

1. How large is the page table and how do we store and access it?

2. How can we speed up translation & access control check?

3. When do we do the translation in relation to cache access?

- There are many other issues we will not cover in detail
  - What happens on a context switch?
  - How can you handle multiple page sizes?
  - ...

Recall: Translation Lookaside Buffer (TLB)

- **Idea:** Cache the Page Table Entries (PTEs) in a hardware structure in the processor to speed up address translation.

- **Translation lookaside buffer** (TLB)
  - Small cache of most recently used Page Table Entries, i.e., recently used Virtual-to-Physical translations.
  - Reduces the number of memory accesses required for *most* instruction fetches and loads/stores to only one TLB access.
Virtual Memory Issue II

- How fast is the address translation?
  - How can we make it fast?

- Idea: Use a hardware structure that caches PTEs \(\rightarrow\) Translation Lookaside Buffer (TLB)

- What should be done on a TLB miss?
  - What TLB entry to replace?
  - Who handles the TLB miss? HW vs. SW?

- What should be done on a page fault?
  - What virtual page to replace from physical memory?
  - Who handles the page fault? HW vs. SW?
Speeding up Translation with a TLB

- A cache of address translations
  - Avoids accessing the page table on every memory access

- **Index** = lower bits of VPN (virtual page #)
- **Tag** = unused bits of VPN + process ID
- **Data** = a page-table entry
- **Status** = valid, dirty

The usual cache design choices (placement, replacement policy, multi-level, etc.) apply here too.
Handling TLB Misses

- The TLB is small; it cannot hold all PTEs
  - Some translation requests will inevitably miss in the TLB
  - Must access memory to find the required PTE
    - Called **walking** the page table
    - Large performance penalty

- Better TLB management & prefetching can reduce TLB misses

- Who handles TLB misses?
  - Hardware or software?
Handling TLB Misses (II)

- **Approach #1. Hardware-Managed** (e.g., x86)
  - The hardware does the **page walk**
  - The hardware fetches the PTE and inserts it into the TLB
    - If the TLB is full, the entry **replaces** another entry
  - Done transparently to system software
  - Can employ specialized structures and caches
    - E.g., page walkers and page walk caches

- **Approach #2. Software-Managed** (e.g., MIPS)
  - The hardware raises an exception
  - The operating system does the **page walk**
  - The operating system fetches the PTE
  - The operating system inserts/evicts entries in the TLB
Handling TLB Misses (III)

- **Hardware-Managed TLB**
  - No exception on TLB miss. Instruction just stalls
  - Independent instructions may execute and help tolerate latency
  - No extra instructions/data brought into caches
  -- Page directory/table organization is etched into the system: OS has little flexibility in deciding these

- **Software-Managed TLB**
  - The OS can define the page table organization
  - More sophisticated TLB replacement policies are possible
  -- Need to generate an exception → performance overhead due to pipeline flush, exception handler execution, extra instructions brought to caches
Three Major Issues in Virtual Memory

1. How large is the page table and how do we store and access it?

2. How can we speed up translation & access control check?

3. When do we do the translation in relation to cache access?

- There are many other issues we will not cover in detail
  - What happens on a context switch?
  - How can you handle multiple page sizes?
  - ...

Teaser: Virtual Memory Issue III

- When do we do the address translation?
  - Before or after accessing the L1 cache?
Address Translation and Caching

- When do we do the address translation?
  - Before or after accessing the L1 cache?

- In other words, is the cache virtually addressed or physically addressed?
  - Virtual versus physical cache

- What are the issues with a virtually addressed cache?

- Synonym problem:
  - Two different virtual addresses can map to the same physical address → same physical address can be present in multiple locations in the cache → can lead to inconsistency in data
Homonyms and Synonyms

- **Homonym:** Same VA can map to two different PAs
  - Why?
    - VA is in different processes

- **Synonym:** Different VAs can map to the same PA
  - Why?
    - Different pages can share the same physical frame within or across processes
    - Reasons: shared libraries, shared data, copy-on-write pages within the same process, ...

- Do homonyms and synonyms create problems when we have a cache?
  - Is the cache virtually or physically addressed?

Modern Address Translation

- L1 Data TLB
- L1 ITLB
- PTW Cache
- PTW Walker
- L2 TLB
- L1 Data Cache
Memory Management Unit

- The **Memory Management Unit (MMU)** is responsible for resolving address translation requests
  - One MMU per core (usually)

- MMU typically has three key components:
  - **Translation Lookaside Buffers** that cache recently-used virtual-to-physical translations (PTEs)
  - **Page Table Walk Caches** that offer fast access to the intermediate levels of a multi-level page table
  - **Hardware Page Table Walker** that sequentially accesses the different levels of the Page Table to fetch the required PTE
Intel Skylake: MMU

https://www.7-cpu.com/cpu/Skylake.html
Intel Skylake: L1 Data TLB
Intel Skylake: L1 Data TLB

- Separate L1 Data TLB structures for 4KB, 2MB, and 1GB pages

- L1 DTLB
  - 4KB: 64-entry, 4-way, 1 cycle access, 9 cycle miss
  - 2MB: 32-entry, 4-way, 1 cycle access, 9 cycle miss
  - 1GB: 4 entry, fully-associative

- Virtual-to-physical mappings are inserted in the corresponding TLB after a TLB miss

- During a translation request, all three L1 TLBs are looked up in parallel

https://www.7-cpu.com/cpu/Skylake.html
L1 Data TLB: Parallel Lookup Example

Virtual Address: 001010100100101010000000000111000000001

- 31st bit to index 1GB
- 22nd bit to index 2MB
- 13-14th bit to index 4KB

L1 1GB TLB
- Set 0
- Set 1

L1 2MB TLB
- Set 0
- Set 1
- Set 2
- Set 3

L1 4KB TLB
Intel Skylake: L2 Unified I/D TLB
Intel Skylake: L2 Unified TLB

- L2 Unified TLB caches translations for both instr. and data
  - private per individual core

- 2 separate L2 TLB structures for 4KB/2MB and 1GB pages

- L2 TLB
  - **4KB/2MB**: 1536-entry, 12-way, 14 cycle access, 9 cycle miss
  - **1GB**: 16-entry, 4-way, 1 cycle access, 9 cycle miss penalty

- Challenge: How can the L2 TLB support both 4KB and 2MB pages using a single structure?
  (Not enough publicly available information for Intel Skylake)
L2 Unified TLB: Accessing the TLB

- The 4KB/2MB structure of the L2 TLB is **probed in 2 steps**

- **Step 1:** Assume the page size is **4KB**, calculate the index bits and access the L2 TLB
  - If the tag matches, it is a hit. If the tag does not match, go to Step 2.

- **Step 2:** Assume the page size is **2MB**, **re-calculate** the index and access the L2 TLB.
  - If the tag matches, it is a hit. If the tag does not match, it is an L2 TLB miss.

- **General algorithm:**
  Re-calculate index and probe TLB for all remaining page sizes

Similar to “associativity in time” (also called pseudo-associativity)
Step 1: Calculate Index for 4KB

Virtual Address

0010101001001010100000000 00011100000001

13-14th bit to index 4KB

L2 TLB

Set 0

Set 1

Set 2

Set 3
Step 2: Re-calculate Index for 2MB

Virtual Address

0010101001001010100000000000111100000001

22th-23th bit to index 2MB

$L2\ TLB$

Set 0

Set 1

Set 2

Set 3
L2 TLB: N-Step Index Re-Calculation

- **Pros:**
  + Simple and practical implementation

- **Cons:**
  - Varying L2 TLB hit latency (faster for 4KB, slower for 2MB)
  - Slower identification of L2 TLB Miss as all page sizes need to be tested

- **Potential Optimizations:**
  1. **Parallel Lookup:** Look up for 4KB and 2MB pages in parallel
  2. **Page Size Prediction:** Predict the probing order

*Tradeoffs are similar to “associativity in time” (also called pseudo-associativity)*
Hardware Page Table Walker

![Diagram showing the relationship between L1 Instruction TLB, L1 Data TLB, L2 Unified TLB, Page Walk Caches, and Hardware Page Table Walker.](image)
Hardware Page Table Walker (I)

- A per-core hardware component that walks the multi-level page table to avoid expensive context switches & SW handling

- HW PTW consists of 2 components:
  - A state machine that is designed to be aware of the architecture’s page table structure
  - Registers that keep track of outstanding TLB misses
Hardware Page Table Walker (II)

- **Pros:**
  + Avoids the need for context switch on TLB miss
  + Overlaps TLB misses with useful computation
  + Supports concurrent TLB misses

- **Cons:**
  - Hardware area and power overheads
  - Limited flexibility compared to software page table walk
Hardware Page Table Walker (III)

- PTW accesses the CR3 register that maintains information about the physical address of the root of the page table (PML4)
- PTW concatenates the content of CR3 with the first 9 bits of the virtual address
Hardware Page Table Walker (IV)

- Hardware PTWs allow overlapping TLB misses with useful computation

**Software PTW**

```
VPN = 1
LOAD A
TLB Miss
Context Switch – TLB Miss Handler
LOAD B
TLB Hit

VPN = 5
```

**Hardware PTW**

```
VPN = 1
LOAD A
TLB Miss
LOAD B
TLB Hit
VPN = 5
```

Page Walk Caches

- L1 Instruction TLB
- L1 Data TLB
- L2 Unified TLB
- Page Walk Caches
- Hardware Page Table Walker
Page Walk Caches

- Page Walk Caches cache translations from non-leaf levels of a multi-level page table to accelerate page table walks.

- Page Walk Caches are low-latency caches that provide faster access to the page table levels compared to accessing the regular cache/memory hierarchy for every page table walk.

Virtual Memory

Summary
Virtual Memory Summary

- Virtual memory gives the illusion of "infinite" capacity

- A subset of virtual pages are located in physical memory

- A page table maps virtual pages to physical pages – this is called address translation

- A TLB speeds up address translation

- Multi-level page tables keep the page table size in check

- Using different page tables for different programs provides memory protection
There is More… We Will Not Cover…

- How to handle virtualized systems?
  - Virtual machines running programs
  - Hypervisors

- Alternative page table structures
  - Hashed page tables
  - Inverted page tables
  - ...

- ...

- ...
Virtual Memory in Virtualized Environments

- Virtualized environments (e.g., Virtual Machines) need to have an additional level of address translation.
Virtual Memory: Parting Thoughts

- VM is one of the most successful examples of
  - architectural support for programmers
  - how to partition work between hardware and software
  - hardware/software cooperation
  - programmer/architect tradeoff

- Going forward: How does virtual memory scale into the future? Four key trends:
  - Increasing, huge physical memory sizes (local & remote)
  - Hybrid physical memory systems (DRAM + NVM + SSD)
  - Many accelerators in the system addressing physical memory
  - Virtualized systems (hypervisors, software virtualization, local and remote memories)

Challenges

• Three examples of the challenges in adapting conventional virtual memory frameworks for increasingly-diverse systems:
  - Requiring a rigid page table structure
  - High address translation overhead in virtual machines
  - Inefficient heterogeneous memory management
Lectures on Virtual Memory

Some Solutions to the Synonym Problem

- Limit cache size to (page size times associativity)
  - get index from page offset

- On a write to a block, search all possible indices that can contain the same physical block, and update/invalidate
  - Used in Alpha 21264, MIPS R10K

- Restrict page placement in OS
  - make sure index(VA) = index(PA)
  - Called page coloring
  - Used in many SPARC processors

More on
Issues in Virtual Memory
Virtual Memory and Cache Interaction
Address Translation and Caching

- When do we do the address translation?
  - Before or after accessing the L1 cache?

- In other words, is the cache virtually addressed or physically addressed?
  - Virtual versus physical cache

- What are the issues with a virtually addressed cache?

- Synonym problem:
  - Two different virtual addresses can map to the same physical address → same physical address can be present in multiple locations in the cache → can lead to inconsistency in data
Homonyms and Synonyms

- **Homonym:** Same VA can map to two different PAs
  - Why?
    - VA is in different processes

- **Synonym:** Different VAs can map to the same PA
  - Why?
    - Different pages can share the same physical frame within or across processes
    - Reasons: shared libraries, shared data, copy-on-write pages within the same process, ...

- Do homonyms and synonyms create problems when we have a cache?
  - Is the cache virtually or physically addressed?

Physical Cache
Virtual Cache
Virtual-Physical Cache

V IPT code

Where can the same physical address be in the code?
Virtually-Indexed Physically-Tagged

- If \((\text{index-bits} + \text{byte-in-block-bits} < \text{page-offset-bits})\), the cache index bits come only from page offset (same in VA and PA)
  - Also implies \(\text{Cache Size} \leq (\text{page size} \times \text{associativity})\)

- If both cache and TLB are on chip
  - index both arrays concurrently using VA bits
  - check cache tag (physical) against TLB output at the end

Diagram:

- VPN to Page Offset
  - Index and BiB
  - TLB
  - Physical cache

- \(\text{VPN} \rightarrow \text{Page Offset} \rightarrow \text{Index} \rightarrow \text{BiB} \rightarrow \text{TLB} \rightarrow \text{PPN} \rightarrow \text{physical cache} \rightarrow \text{tag} \rightarrow \text{data} \)

- TLB hit? cache hit?
Virtually-Indexed Physically-Tagged

- If \((\text{index-bits} + \text{byte-in-block-bits} < \text{page-offset-bits})\), the cache index bits include VPN \(\Rightarrow\) Synonyms can cause problems
  - The same physical address can exist in two locations

- Solutions?
Some Solutions to the Synonym Problem

- Limit cache size to (page size times associativity)
  - get index from page offset

- On a write to a block, search all possible indices that can contain the same physical block, and update/invalidate
  - Used in Alpha 21264, MIPS R10K

- Restrict page placement in OS
  - make sure index(VA) = index(PA)
  - Called page coloring
  - Used in many SPARC processors
L1-D Cache in Intel Skylake

- 32 KB, 64B cacheline size, 8-way associative, 64 sets
- Virtually-indexed physically-tagged (VIPT)
- \#set-index bits (6) + \#byte-in-block-bits (6) = \log_2(\text{Page Size})
  - No synonym problem

- "SEESAW: Using Superpages to Improve VIPT Caches, Parasar+, ISCA’18

An Exercise (I)

We have a byte-addressable toy computer that has a physical address space of 512 bytes. The computer uses a simple, one-level virtual memory system. The page table is always in physical memory. The page size is specified as 8 bytes and the virtual address space is 2 KB.

Part A.

i.  (1 point)
How many bits of each virtual address is the virtual page number?

ii. (1 point)
How many bits of each physical address is the physical frame number?
We would like to add a 128-byte write-through cache to enhance the performance of this computer. However, we would like the cache access and address translation to be performed simultaneously. In other words, we would like to index our cache using a virtual address, but do the tag comparison using the physical addresses (virtually-indexed physically-tagged). The cache we would like to add is direct-mapped, and has a block size of 2 bytes. The replacement policy is LRU. Answer the following questions:

iii. (1 point)
How many bits of a virtual address are used to determine which byte in a block is accessed?

iv. (2 point)
How many bits of a virtual address are used to index into the cache? Which bits exactly?

v. (1 point)
How many bits of the virtual page number are used to index into the cache?

vi. (5 points)
What is the size of the tag store in bits? Show your work.
Part B.

Suppose we have two processes sharing our toy computer. These processes share some portion of the physical memory. Some of the virtual page-physical frame mappings of each process are given below:

<table>
<thead>
<tr>
<th>PROCESS 0</th>
<th>PROCESS 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Page</td>
<td>Physical Frame</td>
</tr>
<tr>
<td>Page 0</td>
<td>Frame 0</td>
</tr>
<tr>
<td>Page 3</td>
<td>Frame 7</td>
</tr>
<tr>
<td>Page 7</td>
<td>Frame 1</td>
</tr>
<tr>
<td>Page 15</td>
<td>Frame 3</td>
</tr>
</tbody>
</table>

vii. (2 points)
Give a complete physical address whose data can exist in two different locations in the cache.

viii. (3 points)
Give the indexes of those two different locations in the cache.
ix. (5 points)
We do not want the same physical address stored in two different locations in the 128-byte cache. We can prevent this by increasing the associativity of our virtually-indexed physically-tagged cache. What is the minimum associativity required?

x. (4 points)
Assume we would like to use a direct-mapped cache. Describe a solution that ensures that the same physical address is never stored in two different locations in the 128-byte cache.
A Potpourri of Issues
Trade-Offs in Page Size

- **Large page size (e.g., 1GB)**
  - **Pro:** Fewer PTEs required → Saves memory space
  - **Pro:** Fewer TLB misses → Improves performance
  - **Con:** Cannot have fine-grained permissions
  - **Con:** Large transfers to/from disk
    - Even when only 1KB is needed, 1GB must be transferred
    - Waste of bandwidth/energy
    - Reduces performance
  - **Con:** **Internal fragmentation**
    - Even when only 1KB is needed, 1GB must be allocated
    - Waste of space
    - **Q:** What is **external fragmentation**?
Some System Software Tasks for VM

- Keeping track of which physical frames are free
- Allocating free physical frames to virtual pages
- Page replacement policy
  - When no physical frame is free, what should be removed?
- Sharing pages between processes
- Copy-on-write optimization
- Page-flip optimization
Virtual Memory in Virtualized Environments

- Virtualized environments (e.g. Virtual Machines) need to have an additional level of address translation.
Shadow Paging

- System maintains a new shadow page table which maps guest-virtual page directly to host-physical page

- Guest-virtual to Guest-physical page table is read-only for the Guest OS

- **Pros:**
  + Fast TLB Miss / Page Table Walk

- **Cons:**
  - To maintain a consistent shadow page table, the system handles every update to Guest and Host page tables

Host Physical Address
Nested Paging

- Nested paging is the widely used hardware technique to virtualize memory in modern systems

- Two-dimensional hardware page-table walk:
  - For every level of Guest Page table
    - Perform a 4-level Host Page table walk

- Pros:
  + Easy for the system to maintain/update two page tables

- Cons:
  - TLB Misses are more costly (up to 24 memory accesses)
